Economic Extraction, Recovery, and Upgrading of Rare Earth Elements from Coal-Based Resources

Michael L. Free, Prashant Sarswat, Landon Allen, Wei Liu, Kara Sorensen
Department of Metallurgical Engineering, University of Utah
Aaron Noble, Gerald Luttrell, Daejin Kim, Morgen Leake
Department of Mineral and Mining Engineering, Virginia Tech
The purpose of this project is to technically and economically evaluate new low cost technology to extract and recover an enriched mixed rare earth element (REE) oxide product from REE-bearing, coal-based resources. This project’s technology begins with selective separation of coal waste resources, followed by heap leaching using biooxidized and conditioned solution, and the resulting extracted rare earth elements are concentrated by solvent extraction and recovered by precipitation to produce a product with 2-8 % REE oxide.
Project Update

• Project updates/accomplishments
  • Industrial participation resulting in 6 different coal waste samples with enriched REE content (total REEs > 190 ppm dry weight basis)
  • Evaluation of separation technologies for rare earth element enrichment in coal waste
  • Demonstration of separation technologies to enrich pyrite for biooxidation
  • Demonstration of heap leaching, combined with biooxidation for extraction of REEs
  • Demonstration of concentration of REEs by solvent extraction
  • Demonstration of iron removal and REEs recovery by precipitation
  • Demonstration of product with 2-8 % mixed REE oxide
  • Presentation of results at Extraction 2018, 2018 AIChE Annual Meeting, and 2019 SME Annual Meeting
Many coal waste materials contain economically recoverable levels of rare earth elements. Coal waste resources from many coal producers contain reasonable levels (200-400 ppm) of rare earth elements in large quantities (millions of tons). The value of the rare earth elements in coal waste is often greater than $0.05 per kilogram ($45/ton) of coal waste.

Utilize low-cost technologies to enable larger resource utilization.

Utilize selective separation technologies to upgrade desired feedstock materials (REE and pyrite).

Utilize heap leaching technology for large-scale, low cost extraction.

Utilize biooxidation and pyrite from the coal waste to provide low cost reagents and rapid leaching as well as to remove residual sulfides from future acid rock drainage.

Utilize solvent extraction and precipitation to concentrate and recover a mixed rare earth element rich product.

Perform a technoeconomic analysis to provide investment and commercialization guidance.
Copper and Gold Processing Scenario

Commercially practiced heap leaching, solvent extraction (or carbon loading), and electrowinning.

- Crushing
- Agglomeration (if needed)
- Crushed ore heap
- Concentration step (solution extraction)
- Recovery step (electrowinning)
- Metal product
- Barren

Ore

Pregnant leaching solution or product laden solution (PLS)
How much does it cost?

For Gold Processing, Bald Mountain Run-of-Mine Heap Leaching/Carbon Ads
  Total Production (2017): 282,000 oz Au
  Total Ore Processed: 34,000,000 tons
  Gold value ($1,250/oz) recovered per ton of ore processed: $10.36/ton

For Copper Processing, Safford Mine Heap Leaching/SX/EW
  Total Production (2015): 202,000,000 lb Cu
  Total Ore Processed: 36,500,000 tons
  Copper value ($2.50) recovered per ton of ore processed: $13.75/ton

These are values without considering profit (often >30 %) and mining costs (usually around 35 % of the total, but previously performed for coal waste). Thus, heap leaching/SX/EW of premined material can be done for $5/ton.
No mining (already assumed for coal waste processing)
Additional processing to remove and concentrate pyrite (+$0.5/ton)
Biooxidation using a separate reactor (+$1/ton est. based on BIOX process)
(to generate consistent acid and ferric ions and avoid temperature control issues that arise with sulfide mineral heap leaching that can have large impacts on microbial populations, precipitation and leaching (sulfides are not commonly found in traditional gold and copper ore heap leach processing)
Separate reactor control of iron precipitation (+$0.5/ton est. from ARD work)
(which may otherwise occur in the heap and cause unwanted passivation and pore plugging. This can be effectively the same process as acid mine drainage treatment.)
No electrowinning (-$1/ton est. based on copper industry information)
General Estimated Cost ($5 + 0.5 + 1 + 0.5 - 1) = $6/ton of coal waste
Bioxidation

Produces acid from sulfide minerals:

$$2\text{Fe}^{2+} + 0.5\text{O}_2 + 2\text{H}^+ \leftrightarrow 2\text{Fe}^{3+} + \text{H}_2\text{O}$$  \hspace{1cm} (Biotic)

$$\text{FeS}_2 + 2\text{Fe}^{3+} \leftrightarrow 3\text{Fe}^{2+} + 2\text{S}_0$$ \hspace{1cm} (Abiotic)

$$2\text{S}_0 + 3\text{O}_2 + 2\text{H}_2\text{O} \leftrightarrow 2\text{SO}_4^{2-} + 4\text{H}^+$$ \hspace{1cm} (Biotic)

Can eliminate future acid mine drainage by consuming pyrite in the ore

Provides ferric ion oxidant for leaching as well as to facilitate iron precipitation

Biooxidation scenario for pyrite using bacteria such as *Acidithiobacillus ferrooxidans*. Note that the dominant mechanism involves indirect leaching. Bacteria are represented by the pink ovals.
Rate of biooxidation

Rates are about 2 grams of ferrous iron oxidized per liter of solution per hour, which results in large reagent savings.

\[
R_{Fe^{2+}ox} = \frac{C_{\text{cells}} \mu_{\text{max}} C_{\text{Fe}^{2+}}}{Y_c (C_{\text{Fe}^{2+}} + K_m)}
\]

Michaelis-Menten kinetics analysis is performed to evaluate performance and equation constants.
14-day small column leaching tests
Preliminary short-term small column leaching results show the anticipated extracted constituents of waste coal using biooxidation based leaching from one source (CR-A).
Large Column Leaching Tests

Large columns are 5 ft. tall, 8 inches in diam. (right side of image). Each column was filled with ~60 kg of crushed coal waste sample. The bottom portion of the column was filled with glass spheres. The flow rate of leaching solution was ~500 ml/day. A fabric filter was also placed on top of the column to distribute the leaching solution.

A schematic diagram showing leaching of coal waste using the large column; and picture of actual leaching solution that is being circulated in column. In few cases leaching solution is not continuously recycled through column. In these cases Eh of the solution is kept maintained and that solution is continuously fed in to the column from top and collected from the bottom.
Column 1: Bacterial leaching solution prepared using 9k media is being circulated continuously. In this case similar solution is collected and sent back again for leaching.

Column 2: In this column also, bacterial leaching solution prepared using 9k media is being circulated. However, in this case the solution is not recycled.

Column 3: In this column also, bacterial leaching solution was used, but pyrite blend nutrient was used. Here the details of such solution:

<table>
<thead>
<tr>
<th>Name of the salt/species</th>
<th>Concentration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Potassium Sulfate</td>
<td>0.88 g/l</td>
</tr>
<tr>
<td>Ammonium Sulfate</td>
<td>0.9 g/l</td>
</tr>
<tr>
<td>Potassium Phosphate</td>
<td>0.25 g/l</td>
</tr>
<tr>
<td>Magnesium Sulfate</td>
<td>0.5 g/l</td>
</tr>
<tr>
<td>Pyrite from Mine sites</td>
<td>100 g/l</td>
</tr>
<tr>
<td>Sulfuric Acid</td>
<td>Added up to pH 1.5</td>
</tr>
</tbody>
</table>

Column 4: In this column 20g/l ferric sulfate solution was recirculated. In this case no 9k media was used. In order to adjust Eh, hydrogen peroxide was used. Initial Eh was ~ 600 mV and pH was ~ 1.5. This is a control test for the chemical oxidation without bacteria.
Leaching extraction for large column (60kg coal waste) fed by biooxidation reactor (35°C) fed using 9K medium with air sparging.
Leaching extraction for large column (60kg coal waste) fed by biooxidation reactor (35°C) fed using pyrite enriched (7% pyrite) coal waste with air sparging.
Large Column Leaching Results

Leaching extraction for large column (60kg coal waste) fed by biooxidation reactor (35°C) fed using 9K medium with air sparging.
Large Column Leaching Results

Leaching extraction for large column (60kg coal waste) fed by biooxidation reactor (35°C) fed using pyrite enriched (7% pyrite) coal waste with air sparging.
Leaching extraction for large column (60kg coal waste) fed by biooxidation reactor (35°C) fed using 9K medium with air sparging. Approximately 5% of the total iron came from the feed solution. The rest came from pyrite dissolution.
Large Column Leaching Results

Leaching extraction for large column (60kg coal waste) fed by biooxidation reactor (35°C) fed using pyrite enriched (7 % pyrite) coal waste with air sparging. Approximately 30 % of the total iron came from the feed solution. The rest came from pyrite dissolution.
Leaching of REEs from coal waste is slow in heaps using biooxidation. It may take one year to reach 30% recovery ($17 value/ton) under current test conditions, which have not been optimized. We believe we can increase the extraction rates and recoveries significantly. Note that finer particles will dramatically increase rates and recoveries, but much finer particles will also make the heaps mechanically unstable, and therefore be more feasible in stirred tank reactors.
Solvent Extraction

\[ Ln_{Total} K \frac{[RH]^3}{[H^+]^3} \]

\[ LnR_3 = \frac{1 + K \frac{[RH]^3}{[H^+]^3}}{1} \]

100 ppm Rare Earth Elements, using D2EPHA.
Precipitation

The primary soluble species with significant concentration levels at pH 0 are metal ions and metal sulfate ions (Fe$^{3+}$, FeSO$_4^{2-}$, Dy$^{3+}$, DySO$_4^{2-}$, La$^{3+}$, LaSO$_4^{2-}$). As the pH rises, the reducing concentration of H$^+$ ions, makes sulfate more available to complex with the metal ions as indicated in Equation 1:

$$H^+ + SO_4^{2-} \leftrightarrow HSO_4^-$$

50 ppm Rare Earth Elements, 2000 ppm Fe. Measured data using ferric sulfate and 100 ppm lanthanum sulfate with titration using NaOH (left) MgCO₃ below
Precipitation

Initial precipitate after removing iron shows enriched rare earth elements.

More than half of the rare earth elements can be recovered by precipitation without solvent extraction.
Summary

Rare earth elements can be recovered in significant quantities from coal waste using low cost technologies that are commercially used on large scales in the gold and copper industries. Additional testing and analyses are being performed to estimate economic and technical viability, but preliminary results show significant potential.
Prearing Project for Next Steps

Market Benefits/Assessment

- This project addresses low cost technologies to extract and recover REEs from coal-based resources with modest levels of REEs
- This program could lead to large scale production of REEs from REE-enriched coal-based resources, which are estimated to be in the hundreds of millions of tons.

Technology-to-Market Path

- Additional testing at a pilot-scale should be performed to refine the process and obtain a more precise estimate of the cost of the process in order to encourage large-scale demonstration and future, widespread industrial utilization.
- The next technological challenge is to design the lowest cost flow sheet and scale-up.
- New research includes using this technology to reprocess tailings.
- Although we have involved industry for samples, partners are needed for scale-up.
