What is Systems Analysis (SA)

Boundaries define the system, methodology defines the analysis

What is Systems Analysis?

“A system is a cohesive conglomeration of interrelated and interdependent parts that is either natural or man-made. Every system is:

- delineated by its spatial and temporal boundaries
- surrounded and influenced by its environment
- described by its structure and purpose or nature
- expressed in its functioning
- can be more than the sum of its parts if it expresses synergy or emergent behavior

Changing one part of the system usually affects other parts and the whole system, with predictable patterns of behavior.”

Systems Science—an interdisciplinary field that studies the nature of systems

Systems Analysis—the branch of systems science that analyzes systems, the interactions within those systems, and/or the interactions with environments

SA of Energy Storage (ES) Concepts

Objectives are often a matter of Use Case and stakeholder perspectives

- **Storage System Owner**

- Generate revenue
 - Energy arbitrage
 - Expanded/enhanced service menu
- Enhance the value of existing assets
 - Increased operational flexibility
 - Decreased production costs

- **Bulk Power System**

- Address changing nature of generator base
 - Increasing replacement of dispatchable with intermittent resources
- Maintain necessary level of critical grid services
 - Reduction of existing base due to retirement of conventional generating resources
 - Compensate for limitations in the “service menu” provided by asynchronous generating technologies

Illustration of Varied “Service Menus”

Conventional dispatchable resources provide a “fuller” menu

WARNING: Relative rankings in table based on specific assumptions and disclaimers documented in white paper—do not use in isolation.
Relative scores are based on “typical” capabilities of resources presently being installed.

Reliable system operation requires online resources aggregately capable of providing the full range of required reliability services.
Synchronous Interconnection resources provide the highest contribution across the broadest range of reliability services.

SA Scope a Function of ES Use Case

System boundaries and parameter granularity are key considerations

- **Unit-Level**

- Stand-alone electricity storage system
- Integrated energy storage system
 - Operationally integrated
 - Physically integrated

- **Bulk Power System-Level**

- Grid
 - Stand-alone
 - Integrated
- Grid+ (i.e., Bulk power system plus co-product markets)

The more relevant the desired analysis outcome, the higher the analysis complexity.

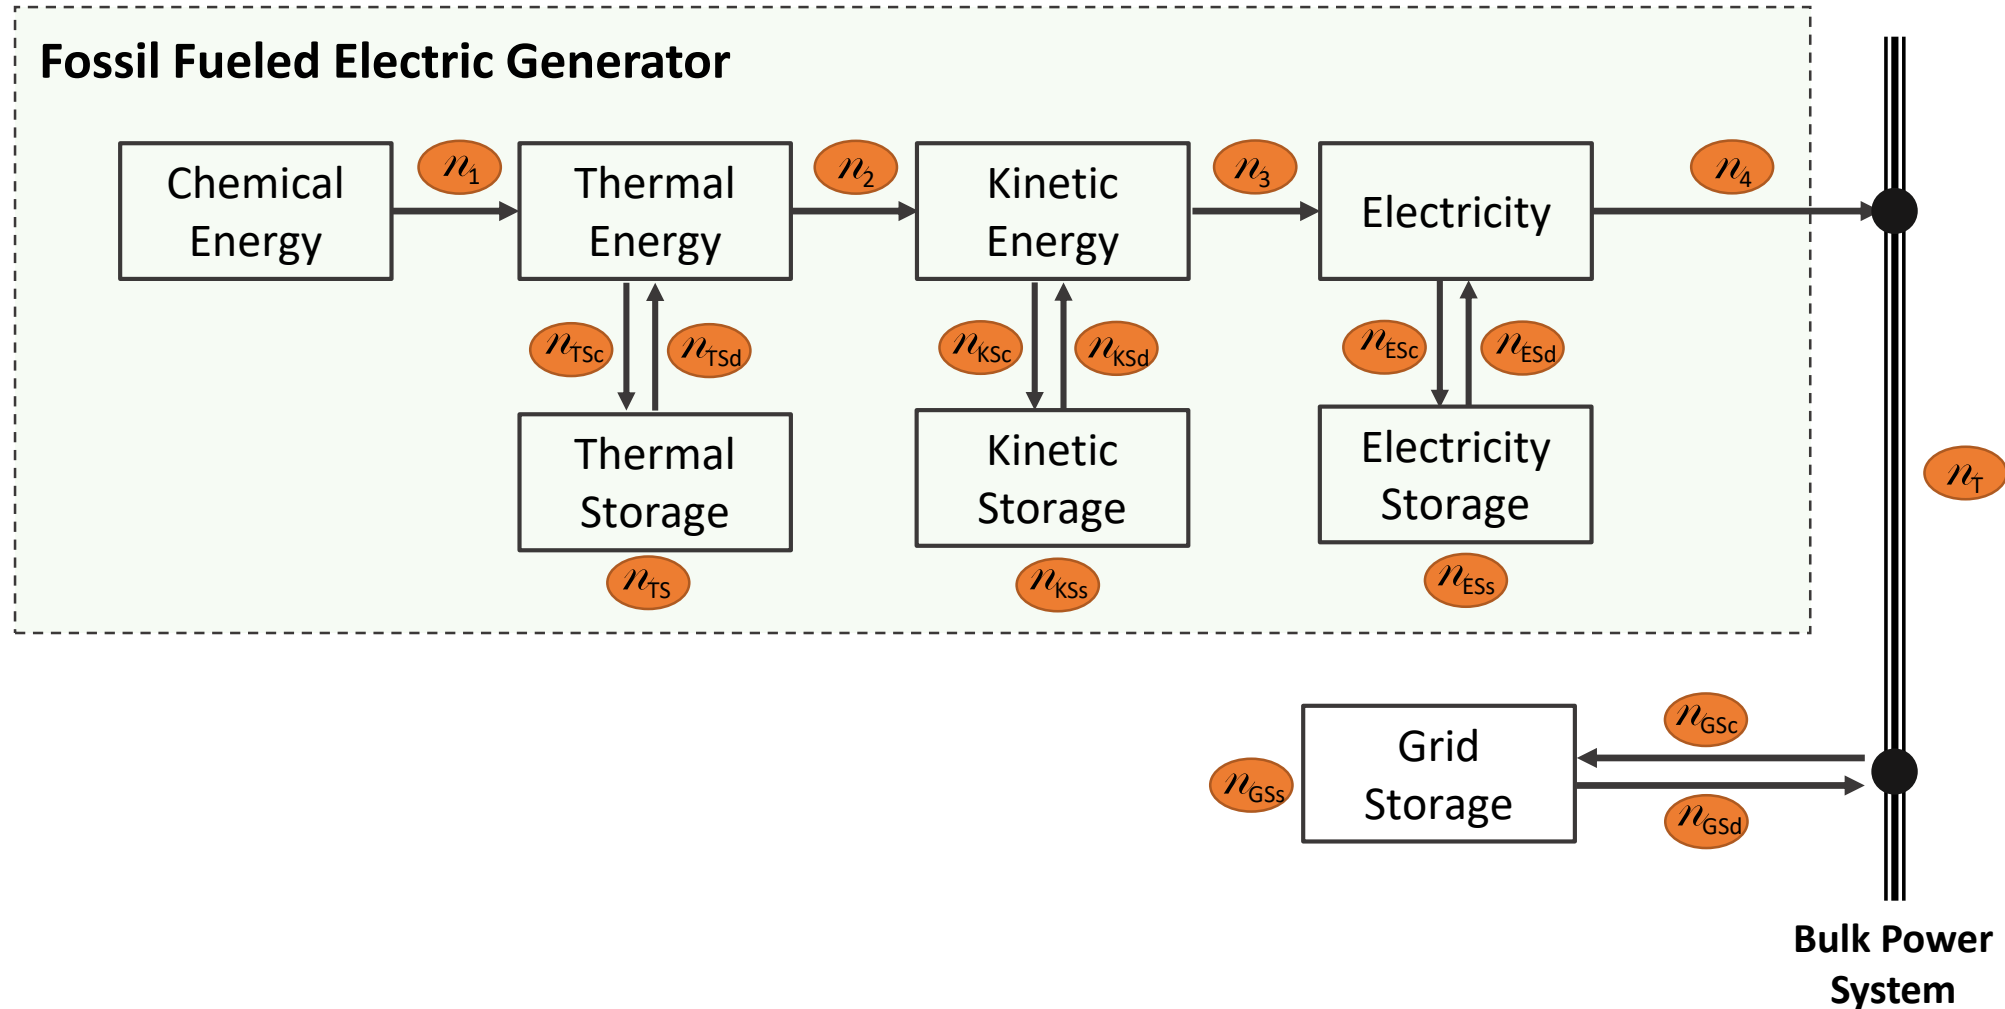

For any analysis outcome to be meaningful, sufficient consideration must be given to determine the appropriate resolution/granularity of:

- Process performance
- Capital and operating costs
- Products/services evaluated
- Locational specificity
 - Supply (including competition) and demand (including alternatives)
 - Supply chain
- Timescale

And more than likely many others ...

Energy Storage Valuation Conundrum

Value is amorphous and ever changing

- The value of pairing energy storage (ES) with generation is less about the product(s) that it provides and more about the flexibility it enables
- Application dependent – ES enables/enhances flexibility attributes differently

Fossil Fueled EGU Attribute Enhancement	Enhancement Opportunity
Energy arbitrage	Low to High
Lower production cost and/or improved energy conversion efficiency	Moderate to High
Expanded product slate	Low to Moderate

- Spatially and temporally dependent – Heterogeneity of how energy is produced, delivered and consumed dictates the demand for and value of flexibility attributes
 - Value Here \neq Value There
 - Value Now \neq Value Then

Quantifying Economic Benefits of Integrated ES

ES offers a range of improvements, many of which are difficult to quantify

• Integrated ES Offers Improved Unit-Level Economics Via

- Lower variable production cost leading to enhanced dispatch capture
- Decreased losses due to out-of-the-market sales
 - ES-enabled energy arbitrage
 - Lower (or avoided) costs associated with taking unit off-line
- Lower maintenance costs due to decreased cycling of process components

Dispatch Capture Opportunity Illustration

Potential dispatch capture from coupling storage with generation could accrue by avoiding out-of-the money sales (and losses) and instead releasing the energy during more valuable periods. The example assumes 10% of unit capacity in coupled storage and energy total storage equivalent to 8 hours.
