

# Blockchain Empowered Provenance Framework for Sensor Identity Management and Data Flow Security in Fossil-Based Power Plants

**Sachin Shetty, Eranga Herath, Roland New, Old Dominion University**  
**Deepak Tosh, Abel Gomez, University of Texas El Paso**

# Project Description

- **Project Goal** - Blockchain empowered provenance platform for **identity management** and **process integrity** for sensors in *Fossil-based Power Plants (FPP)*.
- **Strategic alignment with DOE** - Improving electric grid reliability, resilience and availability
- **DOE-NETL** –Dr. Sydni Credle and Maria Reidpath
- **TEAM**
  - Old Dominion University – Virginia Modeling, Analysis and Simulation Center
  - University of Texas at El Paso – Computer Science
- **Partners**
  - Accenture, Argonne National Lab, ReliabilityFirst, Wood PLC
- **Contract**
  - October 1, 2019 – September 30, 2022

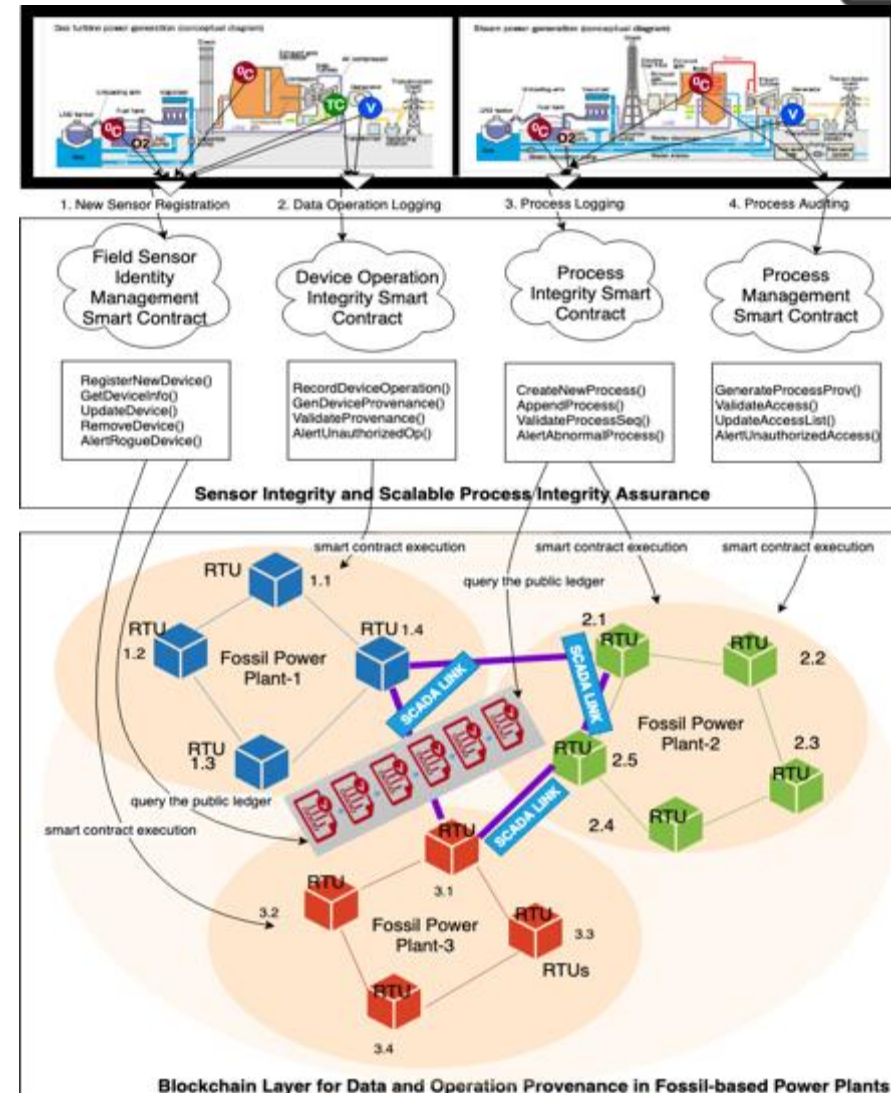

# Project Objectives

**Objective 1** - Sensor **identity management** via establishing a Peer-to-Peer (P2P) SCADA network

**Objective-2:** Networked Sensor Integrity and Scalable **Process Integrity** Assurance in FPPs

**Objective-3:** **Prototype** Development and Evaluation

- Developed Tikiri, a lightweight and scalable Blockchain platform
- Development of testbed using Raspberry Pis and LORAWAN to evaluate Tikiri platform
- Developed data authentication and integrity (SPAI) protocol is using SRAM-based Physical Unclonable Functions (PUF),
- Implemented the SPAI protocol in both Arduino and Raspberry Pi based testbed with DHT11 temperature sensors embedded into the boards
- Developed a lab based SCADA environment composed of HMI and PLCs for prototyping
- Discussions with partners, Accenture, WoodPLC and Argonne National Lab on platform development
- Webinar presentation to the EPRI Utility Blockchain Interest Group
- Submission of papers to IEEE SmartGridComm

# Tikiri - Lightweight and scalable blockchain

- Support real-time transaction
- Concurrent execution of blockchain transactions
- Support sharding based data replication to reduce the communication overhead
- Apache kafka based consensus to increase the scalability and throughput

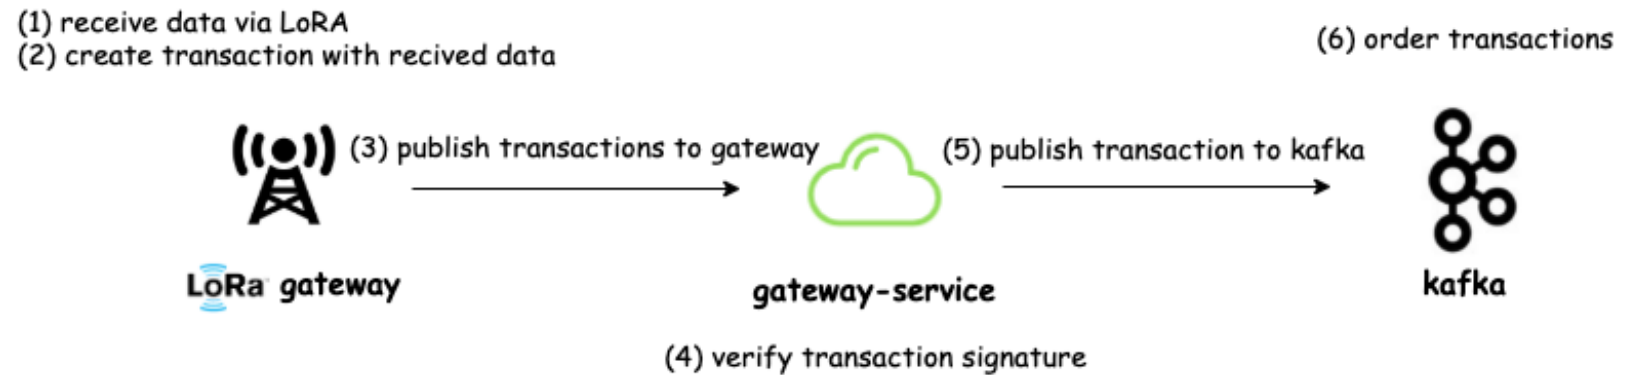

# Tikiri - Lightweight and scalable blockchain

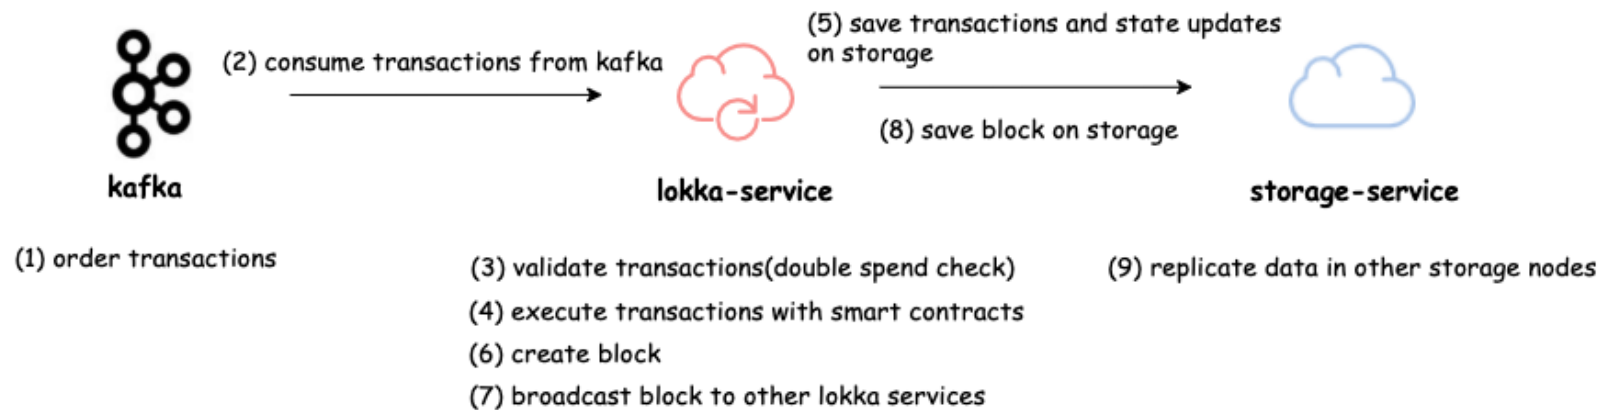

- Microservices based distributed system architecture for lightweight blockchain
- Reactive-streaming based back-pressure operation for scalability

- Blockchain client(e.g LoRa gateway) connected to gateway service and publish transactions.
- Gateway service publishes the transactions to kafka.

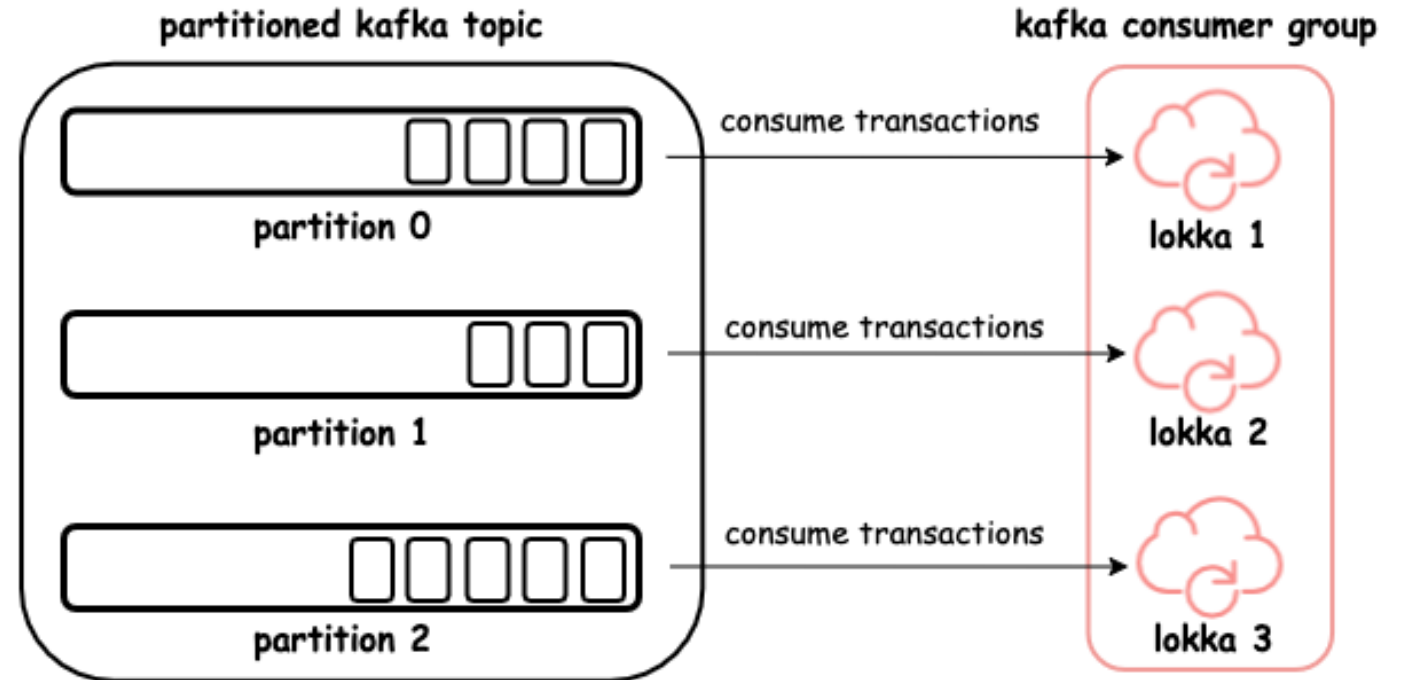

- Lokka services consume transactions via kafka, execute them and create blocks.
- Multiple Lokka services can work in parallel with kafka partitioned topics.

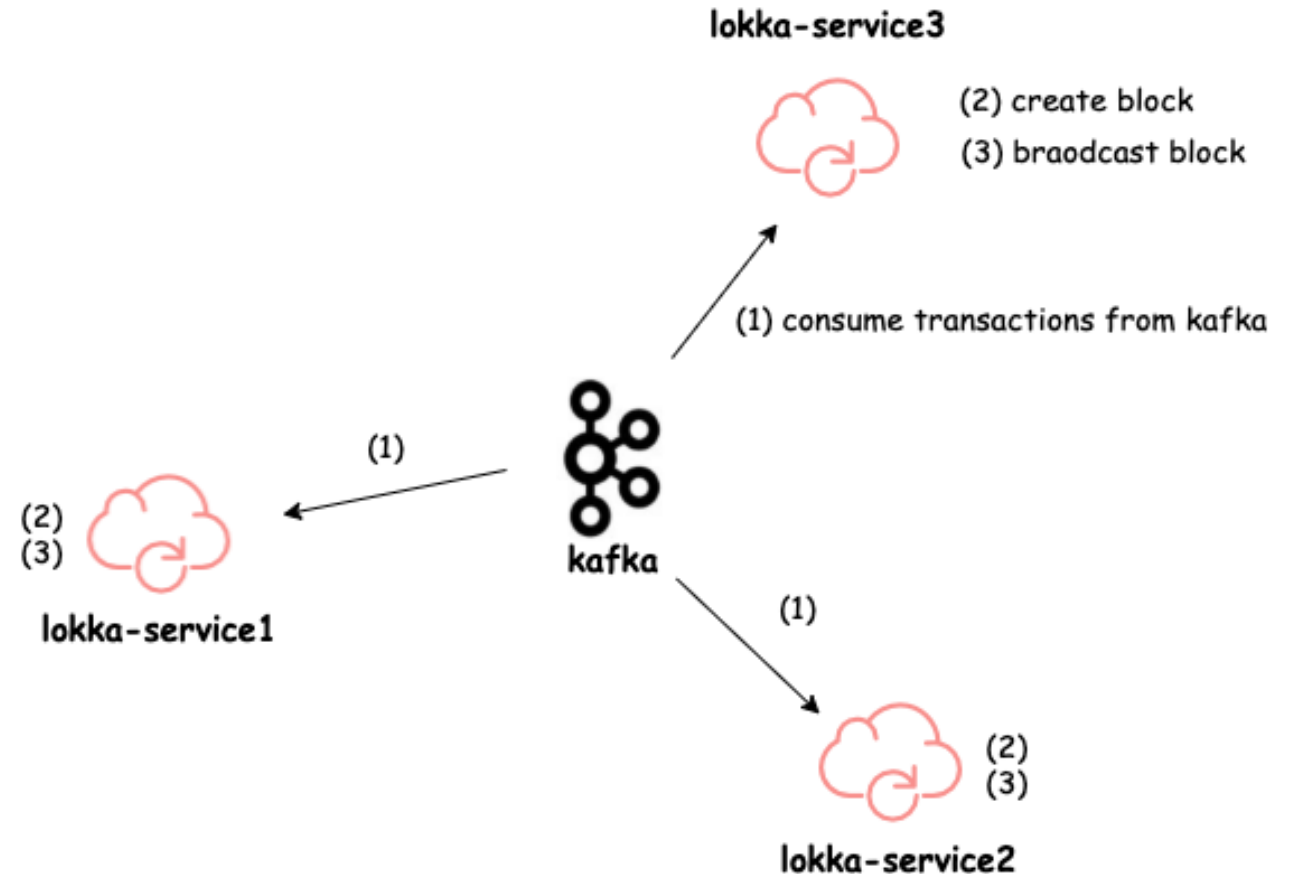

- Kafka will handle message broadcasting between multiple Lokka services by guaranteeing total order

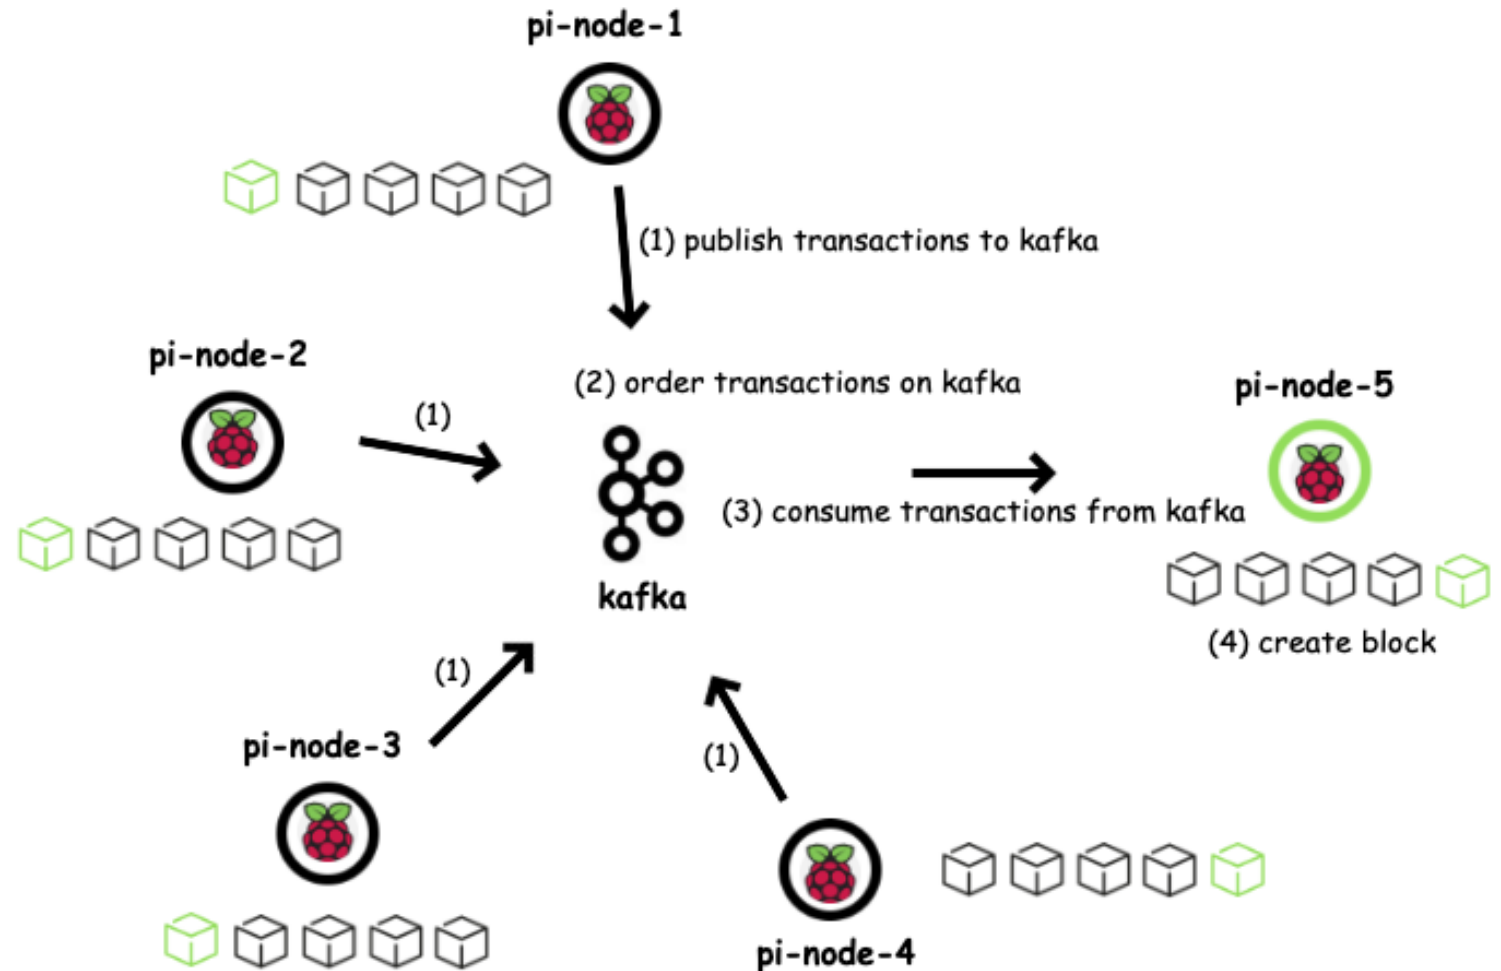

- Execute transactions and create blocks in parallel by multiple Lokka services in Tikiri blockchain.

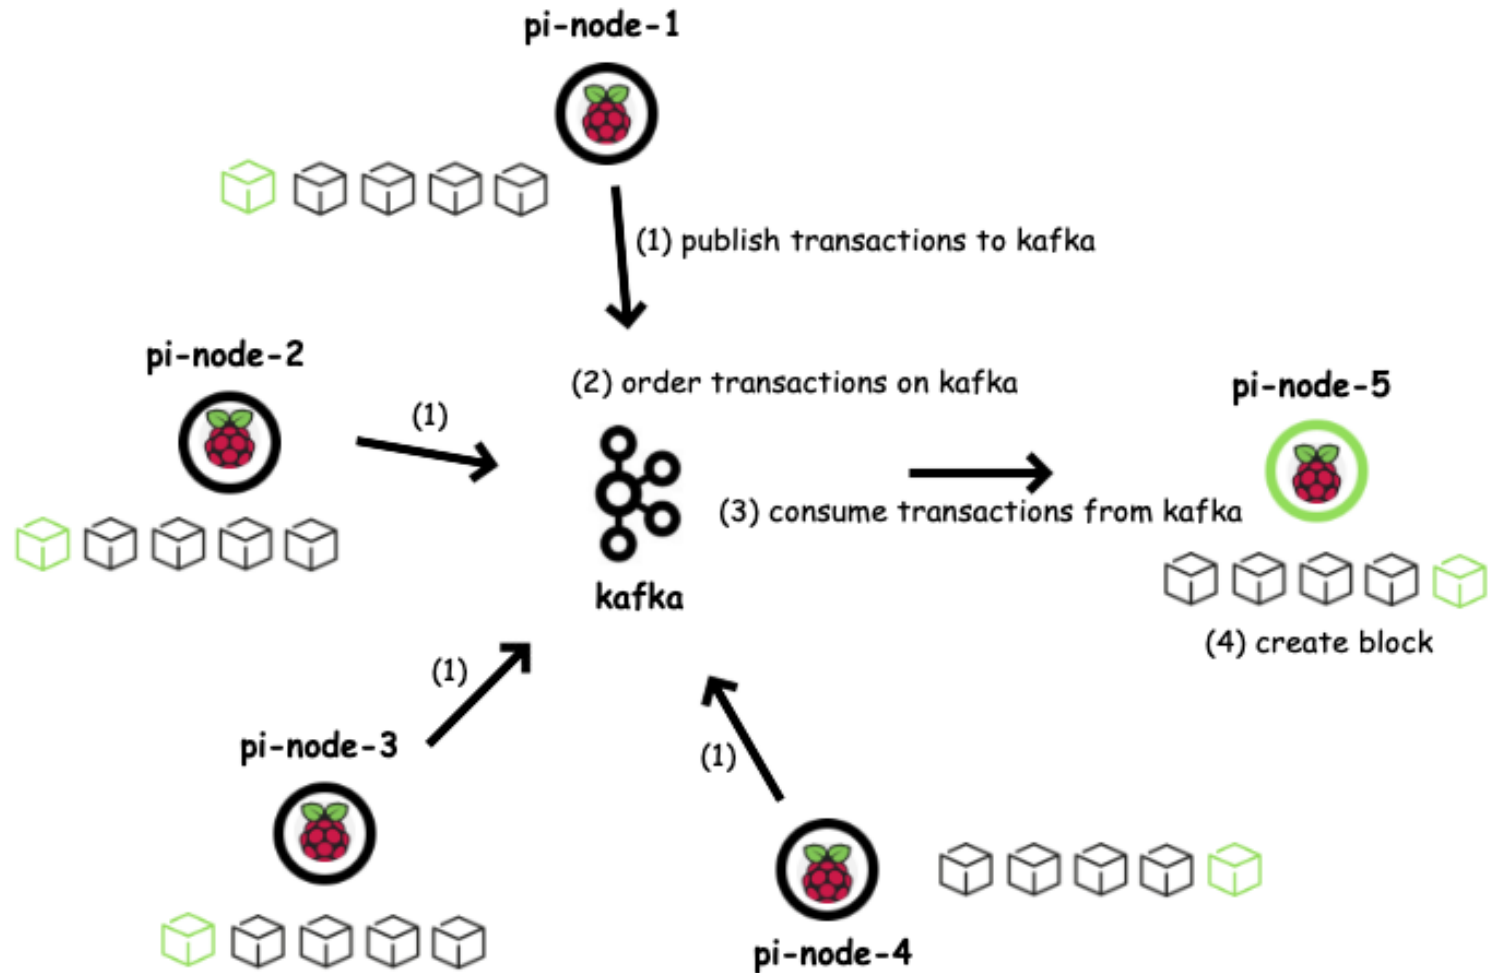

# Tikiri Architecture

- Implemented on raspberry-pi cluster
- Apache kafka (zookeeper atomic broadcast protocol) used as the consensus mechanism
- Functional programming based concurrent smart contract platform

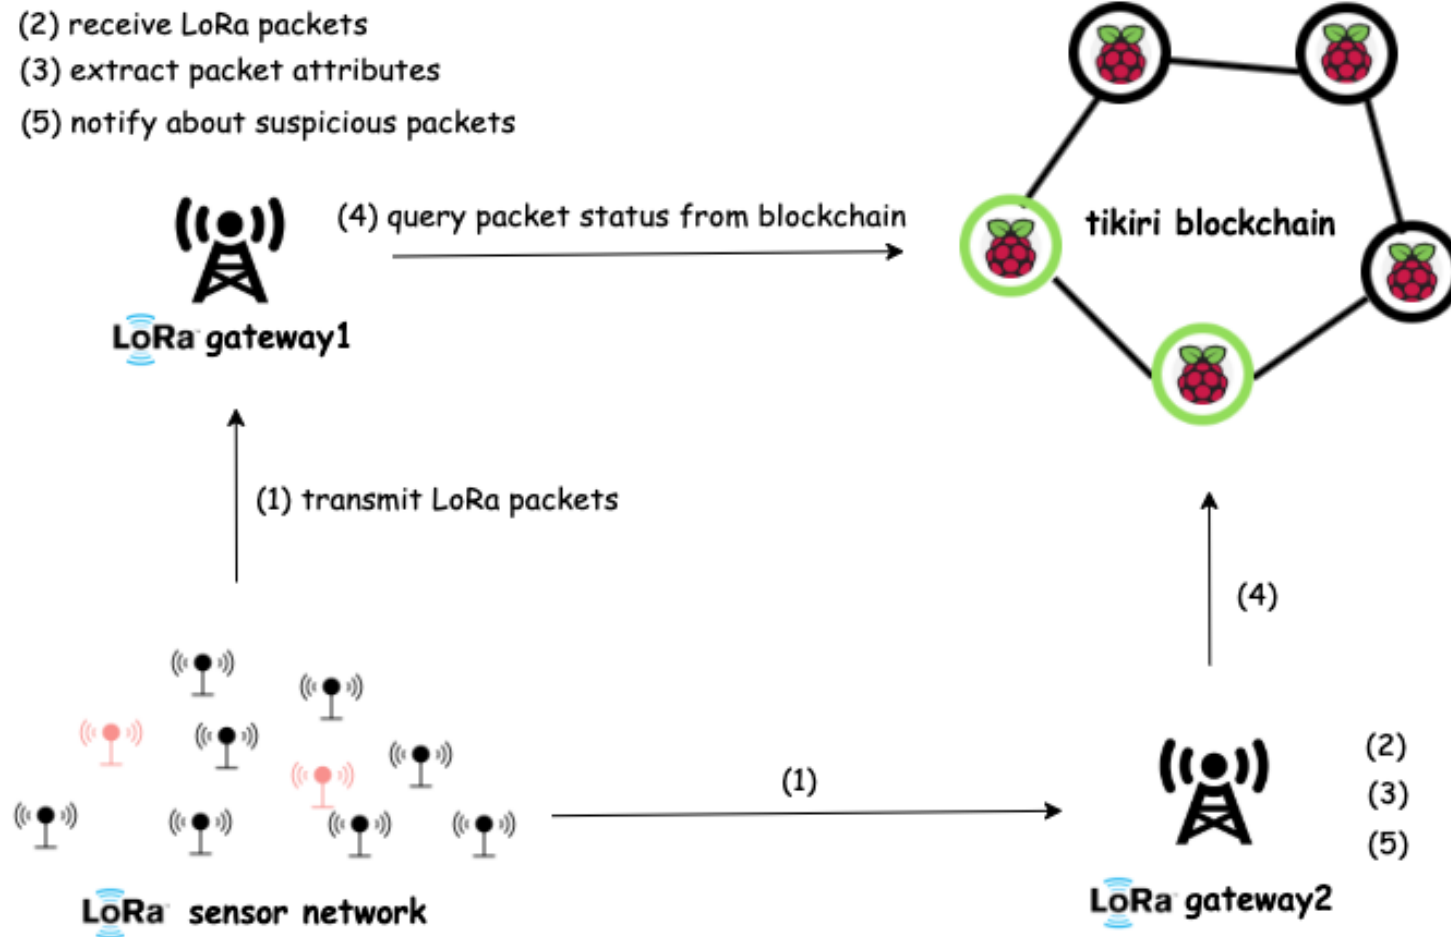

# Tikiri Architecture

- Store power plant sensor device identities in Tikiri blockchain
- Sensor devices communicate with LoRa interface

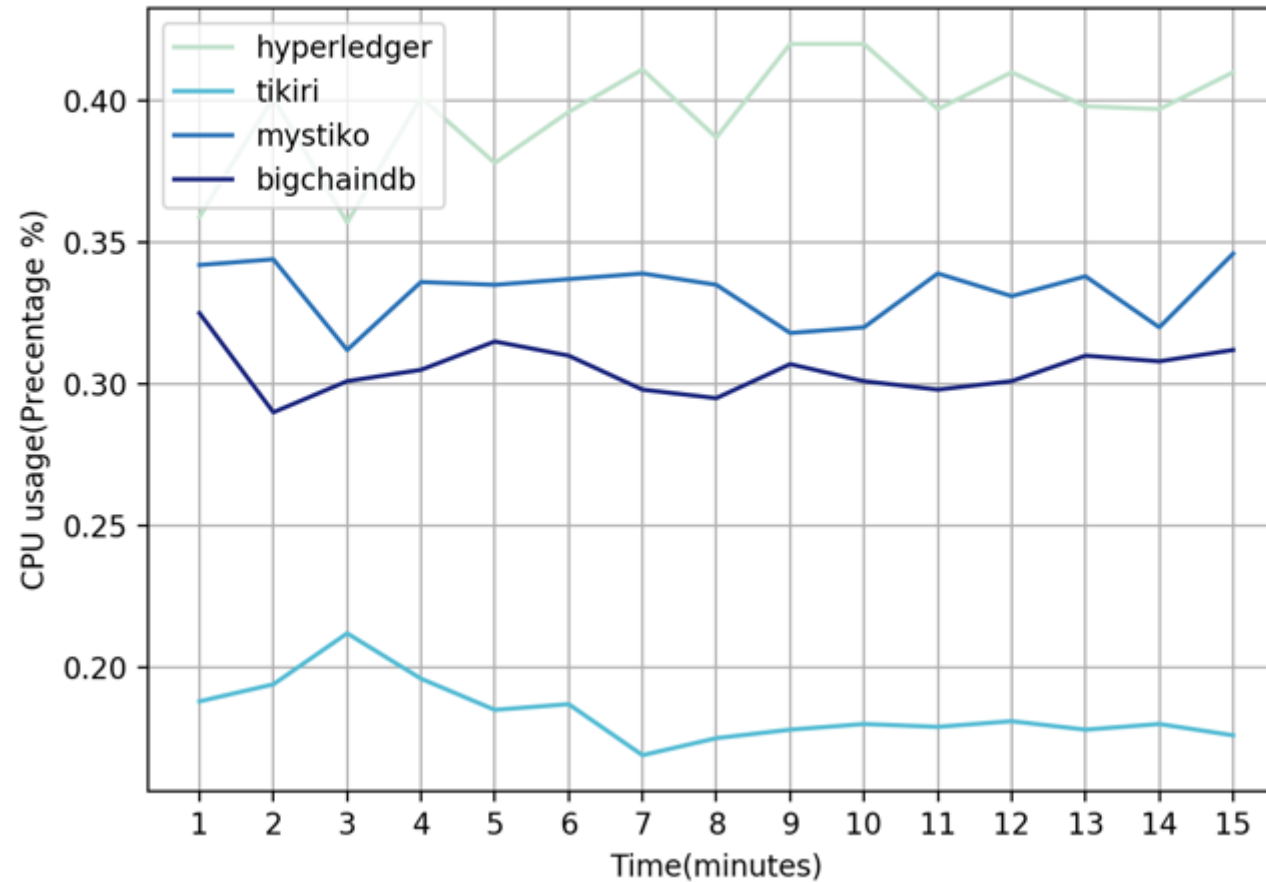

# Tikiri Architecture – Information Flow

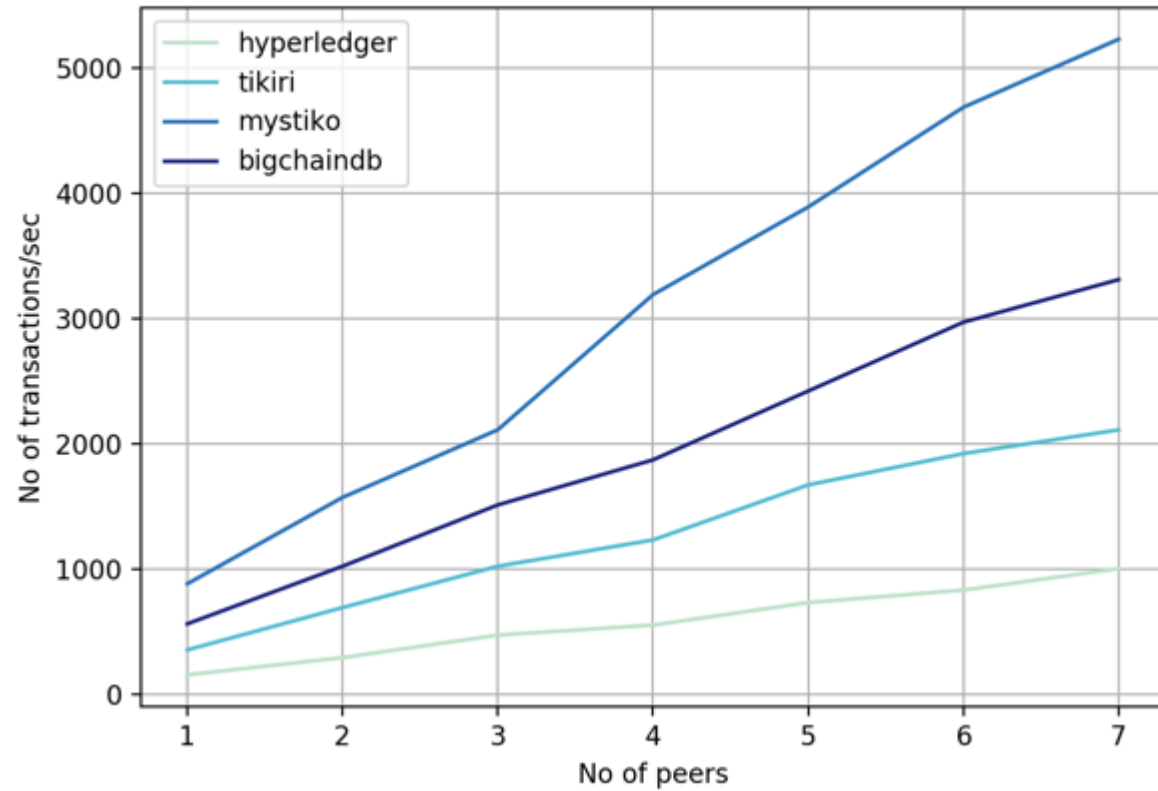

# Tikiri Results – CPU Overhead

# Tikiri Results – Memory Overhead

# Tikiri Results – Scalability

# Tikiri Results – Transaction Throughput

# LoRaWAN Testbed – Sensor network traffic

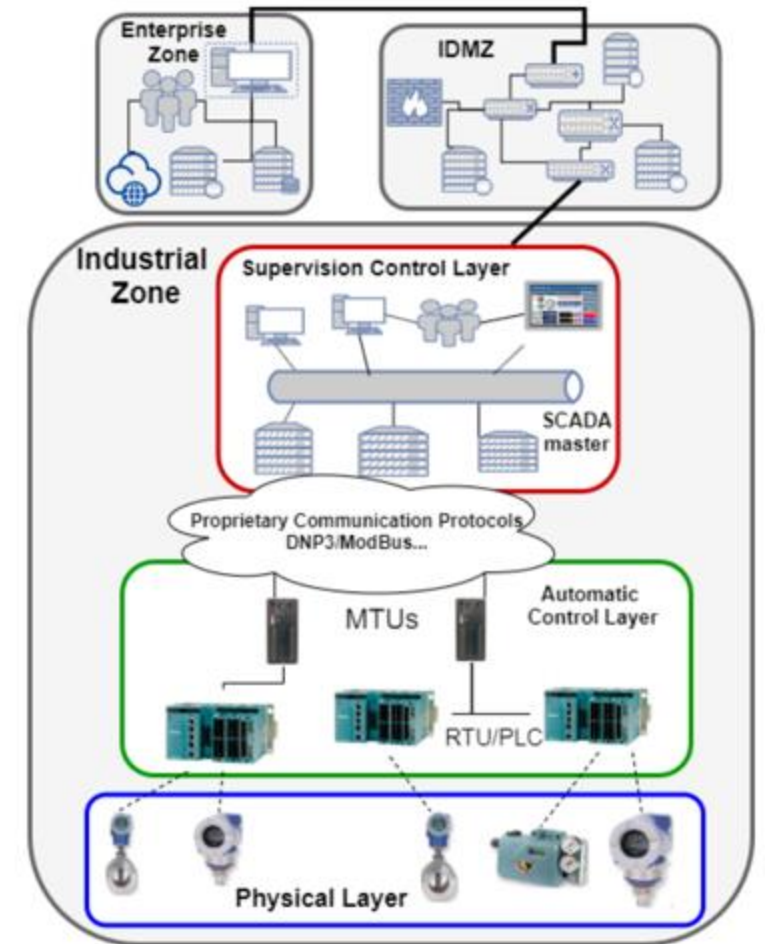

- Represent Industrial IoT Sensor environment
- Provide realistic and reliable generation of end node data
- Transmit end node information to downstream LoRaWAN infrastructure
- Provide oracle services to the Tikiri blockchain

- Current Progress
  - Single Arduino Uno acts as end node and generates/transmits LoRaWAN traffic
  - Single Dragino LG01-P Gateway forwards LoRaWAN traffic to The Things Network (TTN)
  - Gateway packages LoRaWAN traffic and sends to Kafka broker
- Future Work
  - Integration with Tikiri
  - Add additional end nodes & gateways
  - Perform physical layout testing
  - Gather performance metrics
  - Future enhancements (ex: support additional Tikiri communication protocols)

# Sensor Data Authentication using PUFs

- Industrial Control Systems (ICS) are integral components of national critical infrastructures
  - Example: Power plants, Water and gas distribution centers, transportation
- Commonly monitored by Supervisory Control and Data Acquisition (SCADA) systems
- Integration of advanced sensors in power plants introduces security challenges:
  - How to ensure authenticity of sensor data?
  - Can the received data be trusted?
  - What lightweight mechanism can verify device identities in such Cyber-Physical Systems?

## Problem Statement:

Given resource constrained IoT nodes,

How can we uniquely identify them and perform continuous authentication in order to avoid maliciousness (node & data)?

## IDEA:

With **lightweight** hardware security primitive called Physical Unclonable Functions (PUF) to act as a **hardware fingerprint generator** and use it to dynamically authenticate sensor data

# Physical Unclonable Functions (**PUFs**)

A hardware security primitive that maps challenges and responses

$$\gamma: \{0,1\}^n \rightarrow \{0,1\}^m$$

Node	Challenge	Response
Node 1	C1	R1
Node 2	C2	R2
...	...	...
Node N	CN	RN

Authentication server

Physical Unclonable Function (PUF)

- ▶ Challenge-Response
- ▶ Low-cost fingerprint generator
- ▶ Generate unique identities for all devices
- ▶ Offload complex state-of-art crypto solutions
- ▶ Different types such as SRAM-based
  - ▶ High availability and performance [2]

**Offloads the complexity of managing and storing keys  
on the IoT devices**

# Proposed Approach

- We exploit the fundamental property of embedded sensors to generate unique identities through PUFs and derive hash-key functions
- Design a lightweight SRAM-based PUF Authentication and Integrity (SPAI) protocol
  - Ensures the integrity of data flow from field sensors
  - Eliminates rogue devices from the SCADA architecture

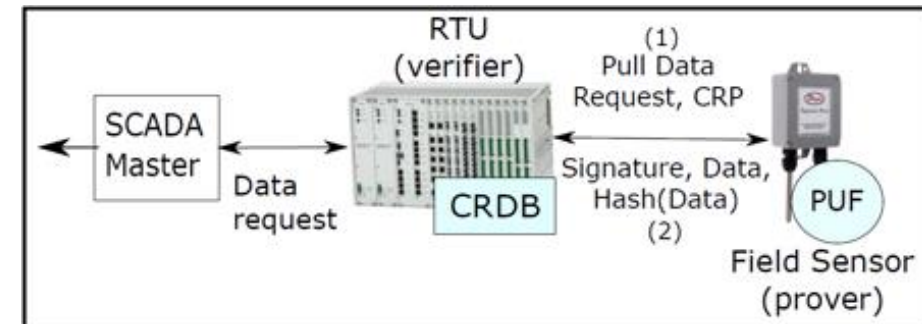

# System Overview

- State-of-art SCADA communication
  - RTU sends a pull request to a field sensor
  - The field sensor read the request and sends the environmental data
  - Operational and commands are sent in clear text without security

- SPAI Protocol Overview

- RTU sends a pull request to a field sensor
- It appends a challenge-response pair from a secure Challenge-Response Database (CRDB)
- The field sensor (prover) uses the CRP to generate a unique response through the PUF
- The prover appends the unique response while sending the sensor data
- The verifier validates the identity of the sensor and integrity of data

- **Three-phase protocol**

- Profiling
- Enrollment
- Authentication

## 1. Profiling

- Error Correction Code, necessary for PUFs introduce a significant overhead
- We identify strongest cells in the SRAM through a Data Remanence Algorithm [4]

## 2. Enrollment: Generate and store CRP

- The verifier gets a challenge and appends it to the CRDB
- Once a challenge is generated, the verifier sends it through a secure channels to the prover
- Using the addresses in the challenge, the prover reads the bit value [0, 1] that is stored in the SRAM, creating a response
- The prover sends the response to the verifier
- Finally, the verifier appends the response to the CRDB

# SPA1 Protocol: [3. Authentication]

- Ensures the authenticity of request and data flow integrity
- Communication during this phase can be over unsecured channels

## Algorithm 1: setup

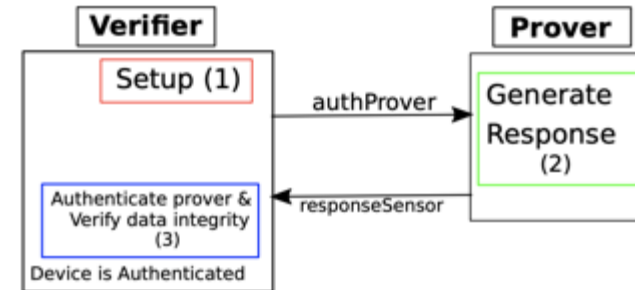

**Require:** Access to CRDB

- 1:  $R_1, C_1 = \text{getTuple}(\text{prover})$
- 2:  $TS = \text{time}()$  // keep track of active requests
- 3:  $H_1 = \text{HMAC}(R_1, C_1 || TS)$
- 4:  $TS' = TS \oplus \text{hash}(R_1)$
- 5:  $\text{respSensor} = \text{authProver}(C_1, TS', H_1)$

## Algorithm 2: generate response

**Require:** Access to PUF mechanism

- 1:  $C_1, H_1, TS' = \text{readRequest}()$
- 2:  $R_1 = \text{getPUF}(C_1)$
- 3:  $TS = TS' \oplus \text{hash}(R_1)$
- 4:  $H_{11} = \text{HMAC}(R_1, C_1 || TS)$
- 5: **if**  $H_{11} \neq H_1$  **then** // verify prover identity
- 6:   **exit**
- 7: **end if**
- 8:  $\text{data} = \text{readSensor}()$
- 9:  $H_2 = \text{HMAC}(R_1, \text{data})$  // ensure data integrity
- 10:  $\text{responseSensor} = \langle \text{data}, H_2 \rangle$
- 11: **return**  $\text{responseSensor}$

## Algorithm 3: authenticate prover and verify data integrity

- 1:  $\text{data}, H_2 = \text{unpack}(\text{respSensor})$
- 2:  $t_2 = \text{time}()$  // keep track of active requests
- 3:  $H_{22} = \text{HMAC}(R_1, \text{data})$
- 4: **if**  $t_2 - TS > \Delta t$  **then** // prevent brute force modeling attacks
- 5:   **exit**
- 6: **else if**  $H_2 \neq H_{22}$  **then** // verify integrity of data and verifier identity
- 7:   **exit**
- 8: **end if**
- 9: **Device is Authenticated**
- 10:  $\text{sendToSCADA}(\text{data})$

# Testbed setup

- Emulated an RTU functions, in a Raspberry Pi 3 model B.
- Raspberry pi is connected to the external SRAM microchip 23LC1024, with a capacity of 128k bits.

- Evaluated the overhead of the SPAI protocol in a temperature and humidity sensor DHT11, the sensor reads and sends the data in every two seconds

## Attack scenario

- Man-in-the-Middle attack
- An attacker has full access to the communication link and message

```
pi@raspberrypi:~/Desktop/sram-puf/Authentication $ ./master

## Performance analysis of the SPAI:

Time to complete authentication process for continuous data stream

## Performance analysis of the SPAI:

Total data communicated over modbus protocol for continuous data stream

- Comparison of performance of different protocols when unit byte of data is communicated and authenticated.

Protocol	Transmission Time	Transmitted Data
Raw Modbus	20ms	857 Bytes
<b>SPAI Protocol</b>	<b>218ms</b>	<b>2803 Bytes</b>
State-of-art PUF protocol [9]	379ms	5483 Bytes

- Scalable data and process integrity assurance in FPP would help plant managers to better maintain the components
  - Reduce operational cost over long-run
- Establishment of overlay Blockchain for SCADA environment can also be applicable for achieving **access control and accountability**
  - Large and multi-site energy companies have many independent contractors, whose access to the infrastructure must be vetted
- **Supply-chain provenance** in energy delivery systems is critical and the proposed platform has potential to enable this service

## Market Benefits/Assessment

- The project addresses the need for an infrastructure based identity management and provenance solution that can provide early detection of rogue devices.
- The proposed technology would realize a low cost security solution that would provide protection to large number of sensors in the power plant and lead to cost savings

## Technology-to-Market Path

- The Blockchain platform will be integrated into state-of-practice security monitoring solutions
- Ensuring the ability to provide desired benefits at lower cost
- Integration with AI solutions to also provide trusted source of ground truth
- Collaborating with Accenture, ReliabilityFirst, WoodPLC

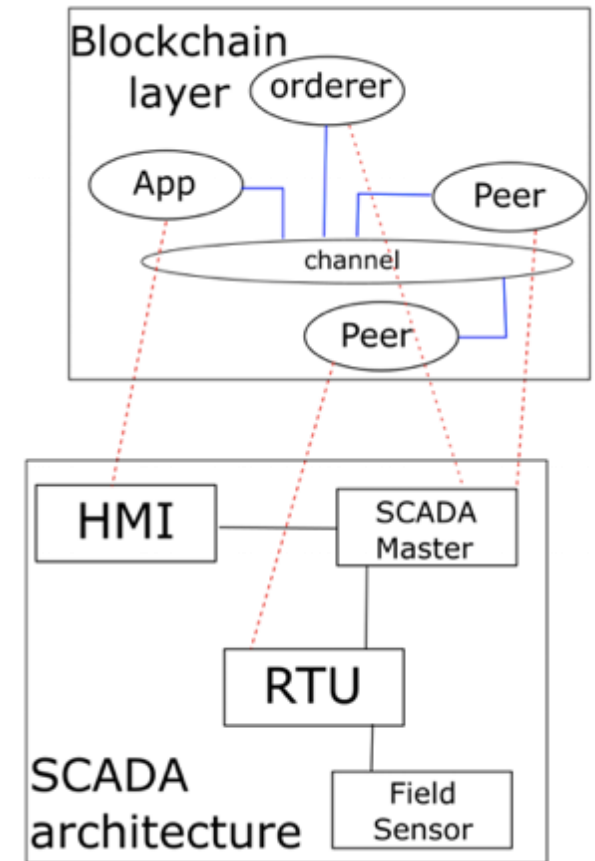

# Concluding Remarks

- The technology developed by the project will address the following specific challenges in fossil energy
  - Identity management and provenance that would enhance the infrastructure cybersecurity.
  - Increasing system reliability due to early detection of attacks
  - Optimize utility efficiency by identifying and isolating faults
  - Enhanced security of monitoring technology by improving resilience to cyber attacks

- We demonstrated that our proposed SPAI protocol is capable of preventing MITM attacks and **detect abnormality in data flow**
- The SPAI protocol **ensures the integrity of sensor data** through HMAC functions and unique PUF-responses. It implements **lightweight crypto** solutions required to improve the security of SCADA systems
- Through preliminary experiments, we found that our proposed SPAI protocol serves its purpose (data authentication and integrity) at a **minimal overhead** compared to existing PUF-based models

# Concluding Remarks and Future Work

- Leverage Tikiri and Hyperledger Fabric Blockchain to store PUF-based sensor identity profiles and authenticate sensor data
  - Performance evaluation for bulk transactions in FPP
- Analyze the overhead induced by Blockchain in terms of storage and time to verify data integrity and improve resilience of SPAI protocol
- Transitioning SPAI to emulated SCADA Network with several OpenPLC controllers interfacing with multiple sensors and actuators

- Support MQTT based communication between sensor network and blockchain network
- Integration with distributed database (Apache Cassandra) to store transaction data
- Integrate off-chain storage to guarantee privacy of the data and address storage issues in the blockchain nodes
- Development of sharding-based consensus that handles the network partitions and failures handling scenarios where the voting nodes that are not reachable
