Outline

Introduction

- Methods
- Results & Discussion
- Conclusion

Water-Energy Nexus

- 83% of electricity in the USA is produced by thermoelectric power plants.
 - Fossil-fuel power plant
 - Nuclear power plant
- Water is a critical component of thermoelectrical plants
 - Electricity generation
 - Cooling

Introduction | Methods | Results & Discussion | Conclusions

3

Alternative Water Resource

- Water scarcity
 - Related to Climate change
 - Caused a drop in electricity production
- Municipal wastewater (MWW)
 - Widespread availability
 - Relatively uniform quality

Projected decreased water resources for thermoelectrical plants

4

Challenges with MWW

- Metal Pollutions in Cooling water
 - Metals introduced from pipe corrosion
 - Metals existing in MWW

There is a strong imperative to frequently monitor heavy metals.

Metal pollutions introduced from the pipes

Introduction | Methods | Results & Discussion | Conclusions

5

Challenges with Metal Detection

- Limitations of mature metal detection techniques
 - Expensive
 - Dedicated staff required
 - Grab-sampling required
 - Lengthy processing

The device that could autonomously conduct metal measurements is desirable.

Anodic Stripping Voltammetry (ASV)

- Advantages
 - Low-cost
 - High sensitivity
 - Easy to be miniaturized
 - Easy to be automated
- Limitation
 - Only ionic metals are ready for ASV detections

Metals in MWW

- Complex with natural organic substances
- Bind with inorganic substances
- Absorbed by various components

Important to develop pre-treatment methods which could release metal ions

Large organic or inorganic substance

Methods

Electrode synthesis

Pretreatment Method Investigations

Electrode Fabrication

- Arsenic detection
 - Au-Fe₃O₄ modified glassy carbon electrode (GCE)
 - Increase conductivity and arsenic sorption ability
- Pb and Cd detection
 - (BiO)₂CO₃-rGO-Nafion modified GCE
 - (BiO)₂CO₃ facilitates the preconcentration of Pb and Cd
 - rGO increases the conductivity
 - Nafion enhances structural stability

Composite material modified GCE

Pretreatment

Acidification

- Dissolve inorganic substances
- Precipitate humic acid

Ultraviolet (UV)/H₂O₂

Produce hydroxyl radicals (*OH)

Results & Discussion

Performances of electrode

Automation

ASV Performances in DI water

- The response peaks increased linearly with increasing concentrations, with well-defined stripping peaks observed.
- The limit of detection is very low (i.e., we could achieve a high sensitivity)
 - Pb: 0.24 ppb << (Discharge limit: 2.5 ppb)
 - Cd:0.16 ppb << (Discharge limit: 0.7 ppb)
 - As: 0.22 ppb << (Discharge limit: 150 ppb)

14

 ASV could directly detect ~900 ppb As(III) in MWW without any pretreatment

 As(III) has a high pKa (9.23), which makes it very mobile.

ASV Performances in MWW

Acidification for Pb detections

 Acidification treatment enabled 12.5 ppb Pb in MWW detected by ASV, while

acidification failed to make Cd detectable.

ASV Performances in MWW

 UV/H_2O_2 for Cd detection

 UV/H₂O₂ treatment made ASV successfully detect most of 3.5 ppb Cd, while it failed to make 12.5 ppb Pb detectable.

Automation

Arduino-based hardwater

Python-based software

Conclusions

Introduction | Methods | Results & Discussion | Conclusions

1.Our nano-material based ASV methods successfully detected all trace As(III) (i.e., ~900 ppb) in wastewater without pretreatment.

2. Acidification (i.e., adjust pH to 1) pre-treatment methods enabled the detection of trace Pb (~12.5 ppb) by ASV in wastewater.

3.A UV/H₂O₂ pre-treatment process enabled the detection of trace Cd (~3.5 ppb) by ASV in synthetic wastewater. However, ASV only measured 78% of Cd in real wastewater, and a systematic error was observed. We will solve it via using glass reactors.

4. The whole process could be automated by integration of open-source software (Python) and open-source hardware (Arduino).
