Phone: 814-865-5813

Email: [ruv12@psu.edu](mailto:ruv12@psu.edu)

**Review Meeting**

April 23<sup>rd</sup>, 2024

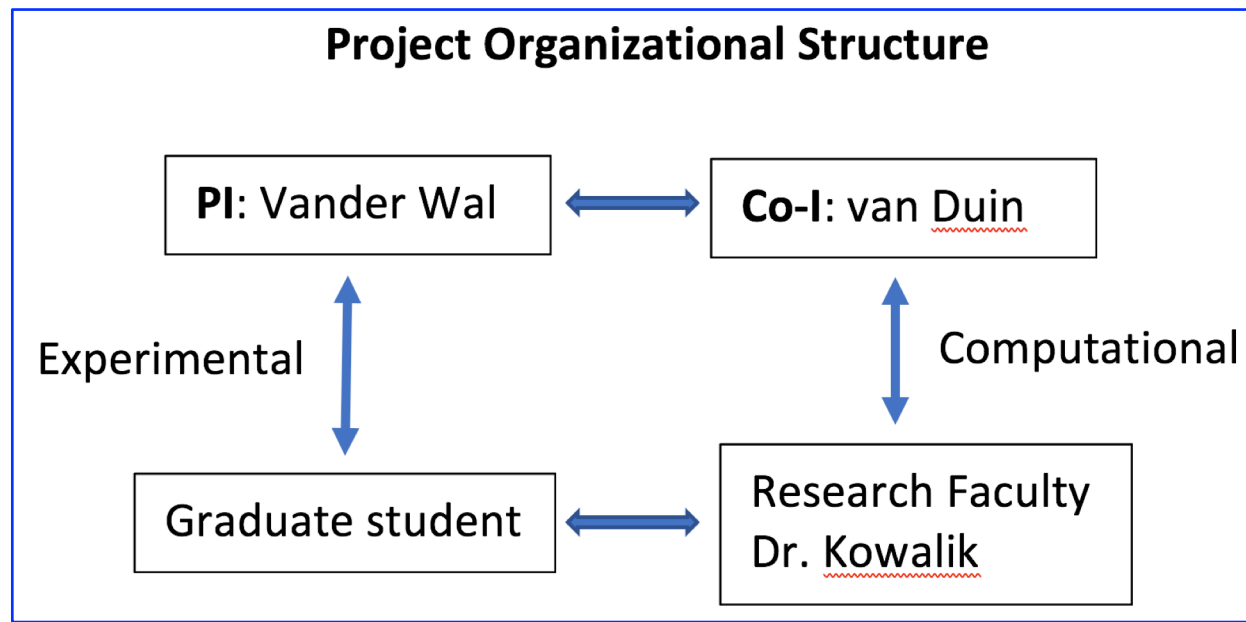

## **Project Organization and Structure: Roles and Responsibilities of Participants:**

Dr. Vander Wal as PI is directing the overall project, manage project personnel, oversee and track budgets, tasks, schedule and be responsible for project deliverables.

Dr. van Duin as Co-PI is providing training in the use of the ReaxFF reactive force field methods – and in connecting ReaxFF results to experiments.

Dr. Kowalik as Co-I is performing simulation development and result assessment.

James Heim II is setting up experimental apparatus and performing tests.

# Technical Background / Motivation for the Project

- Presently hydrogen production is ~ 50 MMT per year worldwide
- ~ 10 MMT of this in the U.S., primarily produced (> 95%) via steam methane reforming [1].

Steam reforming of methane (SMR), the present industrial practice, produces

- 3.7 kg CO<sub>2</sub> (equiv.)/kg of net hydrogen [2]
- consumes 19.8 liters of water per kg of hydrogen [3].

*And requires*

- sulfur removal prior to processing,
- downstream high and low temperature water gas-shift reactions,
- CO removal,
- cleanup of residual CO<sub>2</sub> and H<sub>2</sub>S

*in order to generate a usable H<sub>2</sub> stream.*

# Technical Advantages of Thermo-catalytic decomposition vs. SMR

- TCD does not generate CO/CO<sub>2</sub> byproducts or consume water resources.
- No need for water-gas-shift and CO<sub>2</sub> removal stages.
- Eliminates need along with stock desulphurization and steam generation.
- Energy requirement for methane cracking (37.8 kJ/mole of H<sub>2</sub>) is less than that for steam reforming (63.3 kJ/mole of H<sub>2</sub>) [6].
- Life-cycle assessments [7] and techno-economic analyses [6] are positive.
- Non-catalytic decomposition requires temperatures ~ 1200 °C.
- With catalyst decomposition can be accomplished in the range 850 – 900 °C [8].

# Problem Statement

- $H_2$  may be generated from natural gas by thermo-catalytic decomposition (TCD) or gasification of coal.
- In TCD the reaction rate decreases with time.
- Required temperatures for gasification are high.
- For TCD and regeneration reactions – can an external E-field change the reaction rate? If so, is this due to a change in number of active sites or a change in mechanism and activation energy?

**Approach:** Connect active sites with kinetic rates to differentiate these possibilities and resolve E-field role(s) by reference to atomistic simulations.

# Project Objectives

Project objectives will connect kinetic rates with active sites for thermo-catalytic (TCD) of natural gas and regeneration reactions of CO<sub>2</sub> oxidation of TCD carbon and H<sub>2</sub>O gasification of coal under an applied E-field with parallel ReaxFF-based molecular dynamics simulations for comparisons.

## Objectives:

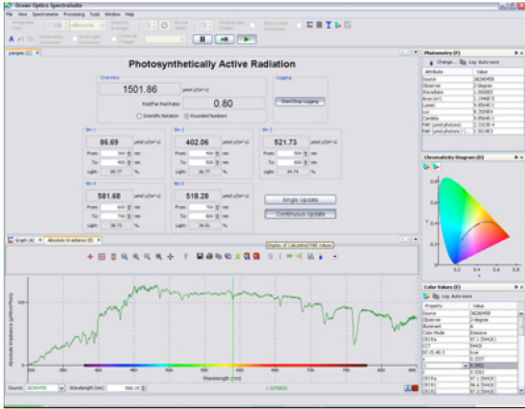

1. Measure active sites parametrically with reaction conditions.
2. Determine reaction rates as function of reaction conditions.
3. Evaluate activation energies for comparison to active site number and type.
4. Develop atomistic simulations for TCD and regeneration reactions for applied E-fields.

# Experimental Approach – Reactions, Rates and Active Sites

- TCD carbon deposition rate will be measured.
- Regeneration will be conducted using CO<sub>2</sub> for CO generation and with H<sub>2</sub>O for gasification.
- (establishing applicability to a coal fed process).
- Regeneration rates will be monitored by products using calibrated analysis methods.

# Joule based Heating

# Active Sites

- XPS has 3 key advantages for active site determination when coupled with chemisorption, compared to TPD – the more commonly used technique.
  - Quantitative for oxygen content (at.%)
  - Better sensitivity ( $\sim 0.1\%$ )
  - Directly measures chemisorbed oxygen rather than derivative reaction products (CO and CO<sub>2</sub>)
- Differentiates oxygen groups, which otherwise can be scrambled by interconversion during the high temperature ramp used in TPD.

# Methane Conversion according to Temperature

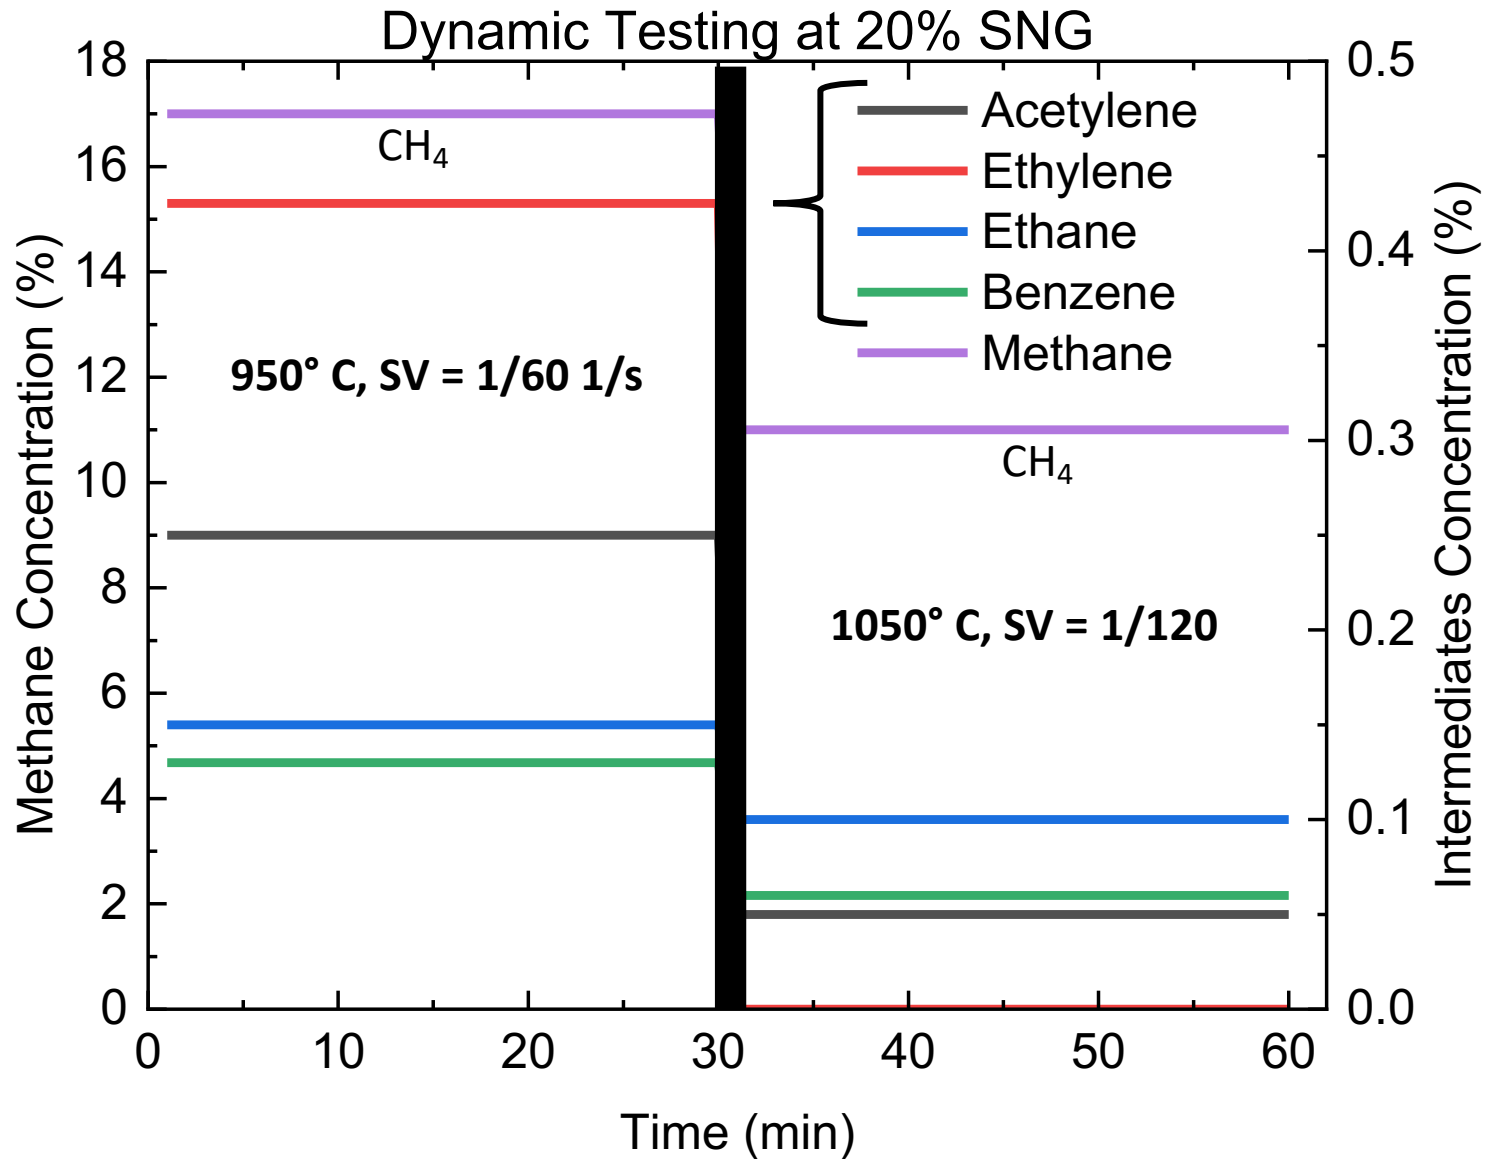

- Constituents of SNG cylinder:
  - 85% methane
  - 10% ethane
  - 5% propane
- With a 20% SNG dilution, Unreacted methane (or zero conversion) is ~17%
- **Methane conversion at various temperatures:**
  - 850° C = ~0%
  - 950° C = ~6%
  - 1050° C = ~35%

$$E_a = 247 \text{ kJ/mole}$$

# Natural Gas Component Specific TCD

# Temperature and Space Velocity Comparisons

# Gasification by 50% CO<sub>2</sub> at 850, 950 and 1,050 °C

Joule heating

By Arrhenius analysis,  $E_a \approx 80$  kJ/mole.

# Comparative Gasification Kinetic Analysis by CO<sub>2</sub>

Ramp rates: 5, 10, and 15 C/min

Furnace heating

Ramp rate compared at iso-conversional levels.

# Carbon TGA Gasification Kinetics

$$E_a = 143.5 \text{ kJ/mol}$$

Activation energy decrease by ~ 2-fold under Joule based heating versus thermal furnace.

# Experimental Summary

## High voltage E-field Configuration

1. Methane decomposition kinetics and activation energy analysis.
2. Component selective TCD wherein only C2 and C3 components undergo TCD while methane remains unchanged in concentration.

## Joule based Heating

1. Structural analysis by Raman spectroscopy of gasified graphite under Joule based heating with reference comparison to furnace heating at 1,000 °C under 50% CO<sub>2</sub> in inert carrier.
2. Structural analysis by Raman spectroscopy of TCD carbon using synthetic natural gas (SNG) with comparison to partial gasification of the same, by CO<sub>2</sub>.
3. Gasification kinetic analysis by CO<sub>2</sub>, determining the activation energy for the Boudouard reaction producing CO. *Preliminary analysis indicates a significant reduction of the activation energy by Joule heating relative to furnace heating via TGA.*
4. Comparative XRD analysis for TCD carbon relative to graphite.

# Next steps

- TCD and regeneration **reaction kinetics** (gasification – H<sub>2</sub>O and reverse Boudouard – CO<sub>2</sub>) will be evaluated as a function of applied E-field strength, and polarity.
- **Active sites** and kinetic dependence upon reactive gases (methane, natural gas, CO<sub>2</sub>, H<sub>2</sub>O) mapping will continue.
- The **nano- and micro-structure** of TCD produced carbons will be further analyzed for E-field differences.
- Further measurements under Joule based heating and high field configurations – supplemented by thermal transfer.

# Connections Between Experiments and Simulations

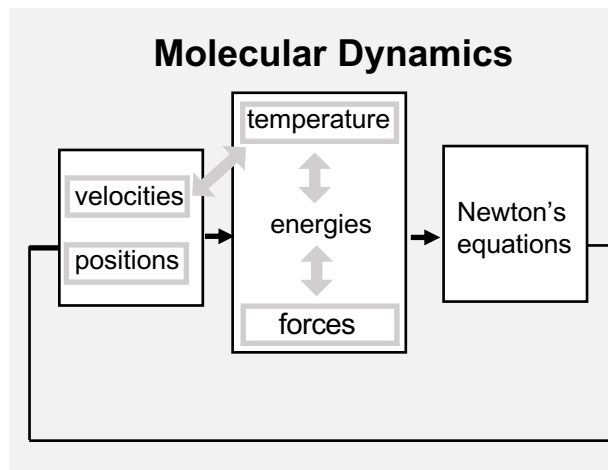

- Activation energy and kinetic metrics will test the hypothesis of the E-field changing the gasification and TCD reaction mechanisms.
- Simulations will provide feedback to experiments for TCD/gasification conditions for **E-field effects upon carbon nanostructure / active sites**.
- Simulations will explore conditions whereby **activation energies and kinetics** are changed in TCD/regeneration by an **applied E-field**.

## Computational Approach: ReaxFF Atomistic Simulations

- ReaxFF combines a bond order/bond distance relationship with a polarizable charge description along with bond-order dependent 3- and 4-body interactions.
- Accurately reproduce reaction energies and barriers, by comparison to DFT-calculations.
- The force field description includes bonded and non-bonded interactions.
- Of particular relevance is the polarizable charge description in ReaxFF.

# ReaxFF/eReaxFF Molecular Dynamics

Molecular Dynamics: deterministic method to model atoms' interactions.

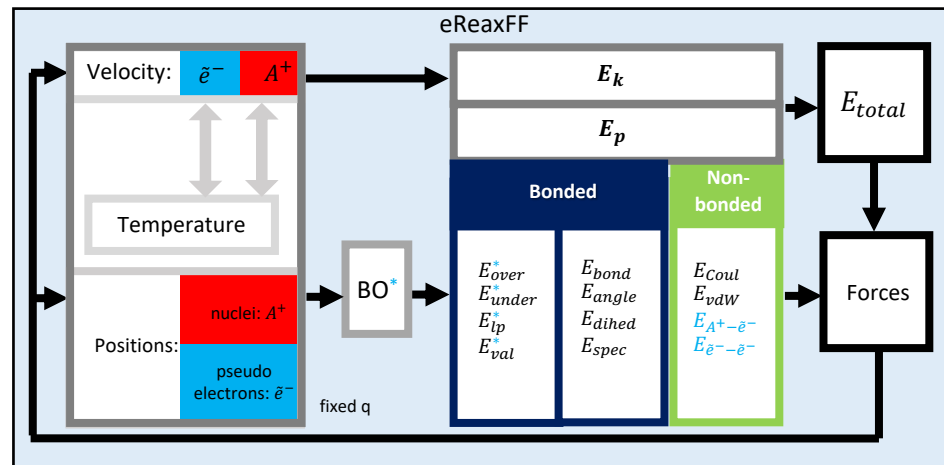

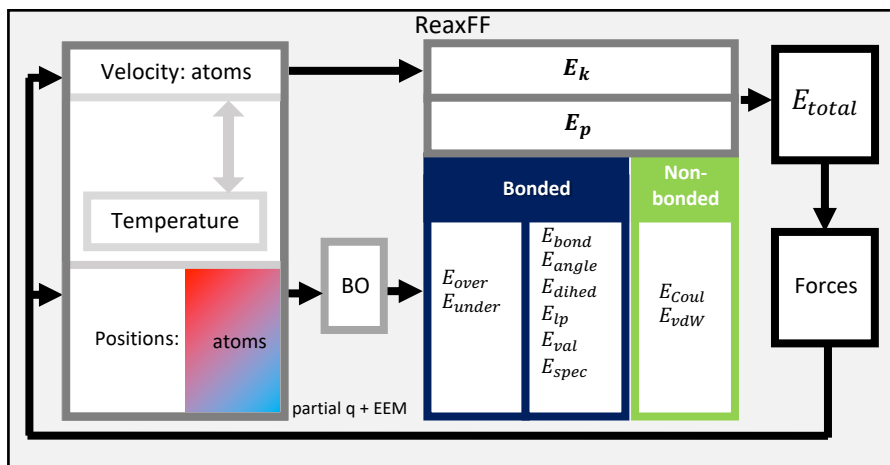

## ReaxFF development tree

Senftle, Thomas P., et al. "The ReaxFF reactive force-field: development, applications and future directions." *npj Computational Materials* 2 (2016): 15011

ReaxFF is an example of the bond order method.

Bond order between two atoms depends on: distance between them and on the local environment.

# ReaxFF Activation Energies

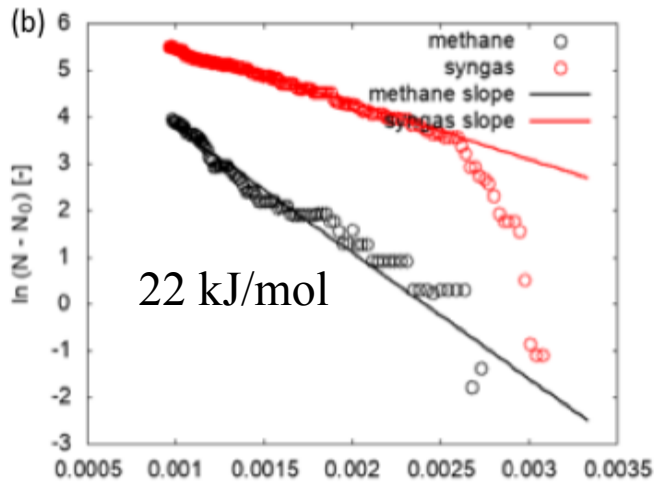

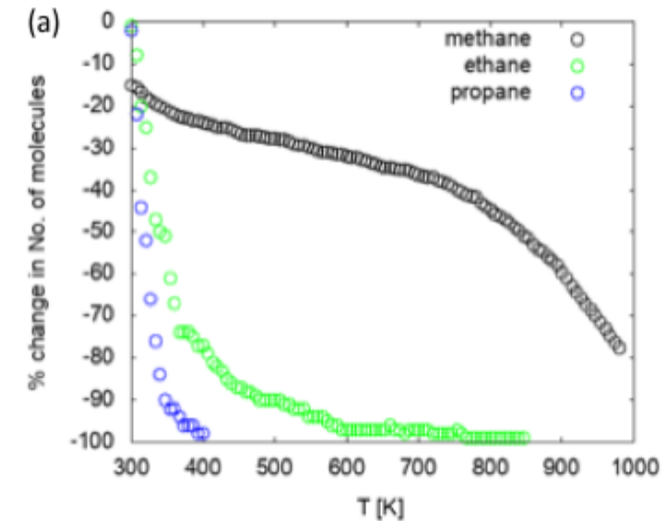

The same trend for activation energy difference for methane vs SNG (methane/ethane/propane with 85/10/5ratio) as in experiment ( $E_a^{methane} > E_a^{SNG}$ ).

Final structures

initial carbon nanostructure  
gas-originated carbon

$$E_a^{methane} = 22 \text{ kJ/mol} \quad E_a^{SNG} = 10 \text{ kJ/mol}$$

# ReaxFF vs DFT data

Good agreement for the binding energies calculated based on the ReaxFF and DFT.

ReaxFF	<b>5.7 kcal/mol</b>	<b>1.3 kcal/mol</b>	<b>2 kcal/mol</b>
DFT	4.8 kcal/mol [1] 5.3 kcal/mol [2]	0.96-1.9 kcal/mol[3]	5-16 kcal/mol [3]

Some of the formation energies might be modify to closer reproduce DFT.

ReaxFF	<b>3.9 kcal/mol</b>	<b>1.25kcal/mol</b>	<b>-1.56 kcal/mol</b>
DFT	-13.4 kcal/mol	-4.6 kcal/mol	-3.9 kcal/mol

[2] Anithaa, V.S. and Vijayakumar, S., 2018. Effect of side chain edge functionalization in pristine and defected graphene-DFT study. *Computational and Theoretical Chemistry*, 1135, pp.34-47.

# eReaxFF vs DFT data

A good agreement for the edge chemistry of graphene for the eReaxFF and DFT [1] data.

[1] Koskinen, P et al. 2008, Self-Passivating Edge Reconstructions of Graphene, Physical Review Letters 101, 115502

It is possible to model local polarization of the functional groups in a presence of external electric field.

# eReaxFF development towards Joule heating modelling

We observe multiple charge transfer between copper electrodes for the copper conducting element even for small  $\Delta V$ .

We observe only one charge transferred from copper electrode to carbon conducting element for small  $\Delta V$ , which localizes at the edge of CNT.

For higher  $\Delta V$  we observe charge transferred from negative copper electrode through CNT to positive one.

We observe a spike in the temperature profile due to charge transfer.

# ReaxFF vs eReaxFF vs DFT

Some changes in the parameter set are still needed for ReaxFF/eReaxFF closer reproduce DFT data.

ReaxFF [kcal/mol]	eReaxFF [kcal/mol]	DFT [kcal/mol]
-5.19		-2.25
3.54	22.05	17.77
-0.095	28.62	15.22
1.4	33.5	17.89

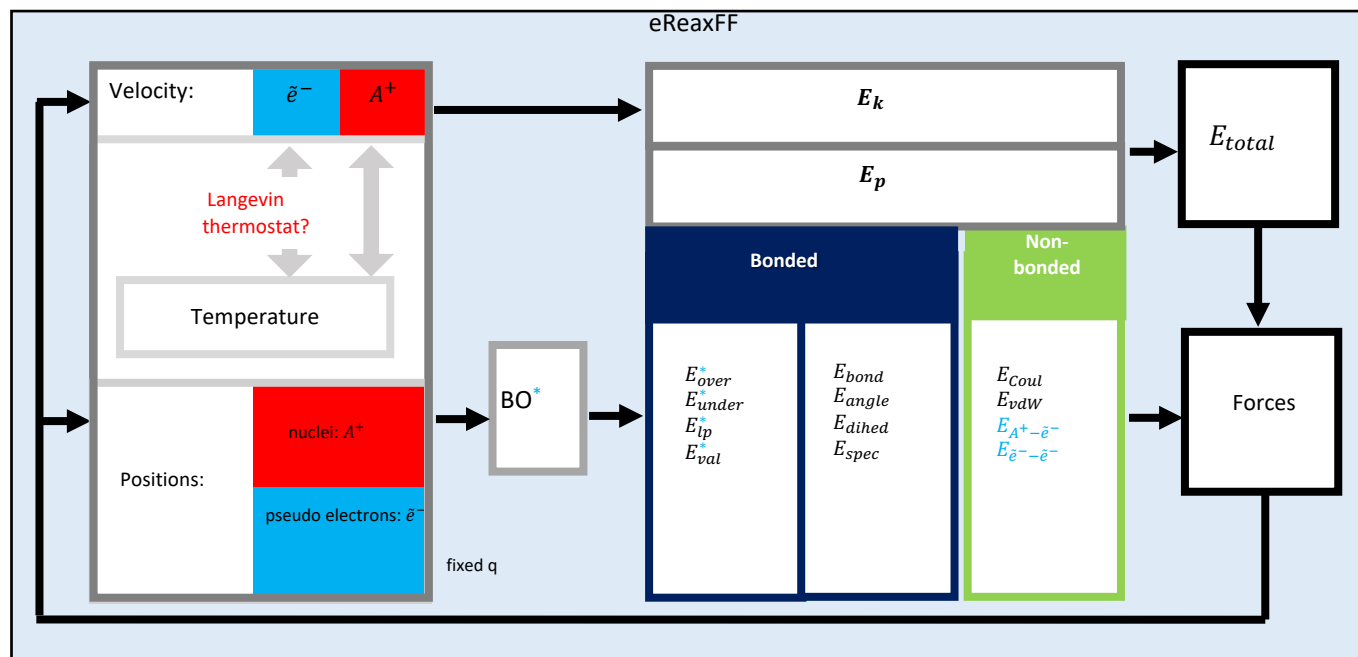

# ReaxFF vs eReaxFF vs DFT

Some changes in the parameter set are still needed for ReaxFF/eReaxFF closer reproduce DFT data.

ReaxFF [kcal/mol]	eReaxFF [kcal/mol]	DFT [kcal/mol]
-7.8		2.68
3.03	21.56	17.04
-0.27	28,44	29.83
1.98	32.92	16.77

# Challenges and Future Work

- To consider reactions with phenol/carbonyl/carboxylic groups;
- To compare the reaction rates for systems with/without E-field to identify a possible atomistic mechanism responsible for lowering the activation energies in the presence of E-field.

# Modeling and Simulation Conclusions

- 1) Tested the ReaxFF capability to identify a difference in the CH<sub>4</sub> vs SNG activation energy;
- 2) Compared CH<sub>4</sub> binding energies for current versions of eReaxFF and ReaxFF to the DFT data.
- 3) Demonstrated the eReaxFF capability to model electron cloud polarization in the presence of an external electric field.
- 4) Tested a possible difference in charge conductance characteristic for copper vs carbon-based material in correlation with local change in temperature.

## Success Criteria and Outcomes

The following questions are applicable to both TCD and (oxidative) regeneration, highlighting their reciprocal nature, and the underlying fundamental role of active sites and E-field enhancement mechanism of carbon surface reactions.

1. As baseline, how do active site number and rate vary with time during TCD and regeneration?
2. Can active site number and rate be controlled by an applied E-field the carbon nanostructure?
3. Can simulations predict and experiments validate conditions wherein regeneration is not needed, i.e., where active sites are (autocatalytically) re-created?

Project success criteria and outcomes will be answers to each of these research questions.

As overall outcome, measurement of active sites and predictions by simulations will provide mechanistic insights for carbon surface reactions relevant to both TCD and regeneration reactions. Beyond the relation between reaction rate and active sites, the primary question of whether the E-field affects active site number and/or type will be addressed for these carbon surface reactions.

# Summary

*This study addresses potential changes in the reaction kinetics and mechanism for TCD and gasification reactions under an applied E-field.*
