Autonomous Monitoring of Wellbore Integrity Applying Time-Reverse Nonlinear-Elastic Wave Spectroscopy and Fiber Optic Sensing and Communication

Project Number (FWP-FE-853-17-FY17)

Presenter: Carly Donahue
PI: Paul Johnson
Earth and Environmental Sciences, Los Alamos National Lab

Project Officer: Kylee Rice
Presentation Outline

- Objective
- Collaborators and Background
- Approach
- Impact
- Technical status
- Accomplishments to date
- Lessons learned
- Synergy opportunities
- Project summary
Goals and Objective: Development of an autonomous system that can be deployed in wells for unattended long-term (e.g., decades) to monitor both wellbore integrity and stress changes around the borehole

- Need: affordable, robust, autonomous system for monitoring wellbore integrity, especially post closure
- Need: detect leakage signatures for long term CO₂ monitoring

Innovation: Combination of:

(i) Fiber optic sensing to track near-borehole anomalous stress evolution associated with damage

(ii) Active acoustics using embedded sensors and Time Reverse Nonlinear Elastic Wave Spectroscopy (TR-NEWS) to probe for localized damage

(iii) Machine learning to extract passive seismo-acoustic signals for long term monitoring of associated with leakage;
Collaborators and Background

Team
Los Alamos National Lab (project lead)
  • P. Johnson (PI), G. Guthrie (co-PI), J. TenCate, C. Donahue, M. Remillieux, B. Carey, M. Stuber-Geesey
  • Acoustics (nonlinearity, time reversal, signals from noise); machine learning; wellbore integrity; lab-scale experiments; project integration

Lawrence Berkeley National Lab
  • K. Nihei, S. Nakagawa
  • Acoustics; fiber optics

Clemson University
  • L. Murdoch, L. Hua, H. Xiao, S. DeWolf
  • Fiber optics, geomechanics, acoustics

Chevron, ETC
  • H. Goodman
  • Field application needs

Background to Approach
Our previous work has demonstrated:
  • Machine-learning algorithms can extract small seismo-acoustic signatures from noisy backgrounds;
  • Nonlinear acoustic methods can probe damage (distributed & localized) in complex earth materials;
  • Acoustic time-reversal methods can be used to focus energy (including within earth materials);
  • Fiber optic sensors can be used to monitor strain at high resolution;
  • Microwave photonics can measure distributed strain with optical fiber using non-proprietary methods.
Approach

A. **Listen** for leakage related signatures in the near-wellbore region using passive acoustic methods (specific objective 1; task 3)
   
   i. Identify/discover signatures
   
   ii. Evaluate ability of embedded acoustic sensors to detect signature(s)

   iii. Develop machine-learning algorithms to extract signature(s) autonomously, including the extraction of signal from noise

B. **Interrogate and locate** damage regions with time-reversal nonlinear elasticity wave spectroscopy (TR-NEWS)
   
   i. Demonstrate the ability to focus acoustic energy at specific points along a wellbore using time reversal (specific objective 2; task 4)

   ii. Use time-reversal to locate damage (specific objective 3; task 5)

C. **Monitor** strain/stress evolution in near-wellbore region using fiber optic sensing
   
   i. Demonstrate the ability of an embedded fiber optic cable to detect strain tied to loss of integrity in the near-wellbore region (specific objective 4; task 6)

   ii. Evaluate the feasibility of measuring distributed strain and acoustic spectra using non-proprietary fiber optic techniques
**Task 3—Detection of Fluid-Flow in a Damaged Wellbore**

**Distributed Acoustic Signals: Coherence Microwave Photonic Interferometry (CMPI)**

**Objective**
Develop/demonstrate optical methods for measuring acoustical signals
- Frequency to 20 kHz
- Spatially distributed
  - Many locations
  - High spatial resolution
  - High strain sensitivity
- Potential for low cost implementation
- Off-the-shelf components
- Open source signal processing

**Approach**
- Microwave photonics: Novel optical method developed at Clemson University
- Improve speed and resolution → CMPI

**Signal Processing**
- Microwave phase to locate reflector pairs in time domain
- Optical interference pattern in time domain
- Correlate interference intensity to acoustic wave amplitude and frequency
Task 3—Detection of Fluid-Flow in a Damaged Wellbore

Proof-of-concept CMPI lab experiments

Objective: Demonstrate that CMPI can measure frequency and amplitude of an acoustic signal at multiple locations along a casing.

Column filled with sand with axial casing

- Reflectors spaced 0.15m apart used as sensors to measure acoustic signals at 7 locations along a casing in sand
- A speaker produces acoustic signals of different frequencies, so the acoustic spectrum at various locations can be measured by the distributed sensors
Task 3—Detection of Fluid-Flow in a Damaged Wellbore
Proof-of-concept CMPI lab experiments

Acoustic spectra at 7 fiber reflector locations

Amplitude of the acoustic wave attenuates along the pipe

Example acoustic spectra at reflectors R2 and R3
Task 4—Use of Time Reversal to Focus Energy along a Wellbore

Time reversal experiments in a lab-scale borehole

The first step is to see if we can focus acoustic waves next to an experimental wellbore. It works!

- fiber optic vibrometer
- transducers
- focus point
- scanning vibrometer
- scan area
- velocity
- peak delayed as amplitude increases
2D Cement-Crack Model

- Arbitrary geometry crack in cement
- Sources (S₁-S₁₃) are 1” in length and distributed every 0.1 m along outer edge of steel casing
- Receivers (R₁-R₁₂) are point probes located between sources
- Rayleigh damping in cement (α = 500, β = 1.27e-7)

Task 5—Nonlinear Responses Associated with Damage

Initial focus: Use synthetic data to assess nature of a nonlinear signal in a damaged wellbore system.
Task 5—Nonlinear Responses Associated with Damage

2D Cement-Crack Model

Source Signal

- Centered at 10 kHz
- Pulse is sent at one source
- A simulation will be run for each source
- Received signal is recorded at all receiver locations (R₁-R₁₂) during each simulation

Time

- Each simulation models 20 ms of behavior with $\Delta t = 1e-7$ s
Task 5—Nonlinear Responses Associated with Damage

Modeling a Crack

- A crack is modeled by a nonlinear spring at the interface.

- The spring force is distributed over the crack interface.

- At one instant, one portion of the crack may be closed while another may be open, depending on the loading.

- The spring force depends on the elongation between the crack faces.

\[
\text{Stiffness, } k = k(\delta L)
\]
Task 5—Nonlinear Responses Associated with Damage
Modeling a Crack

- Propagation of a wave with sufficiently large amplitude through a crack generates a nonlinear elastic response.
Task 5—Nonlinear Responses Associated with Damage

Preliminary Results: Particle Velocity

- Propagation of a wave with sufficiently large amplitude through a crack generates a nonlinear elastic response. Towards the end of the simulation, we see the crack acting as a secondary source of high-frequency vibration.
Task 5—Nonlinear Responses Associated with Damage
Preliminary Results: NL TR Processing

We repeat this process for all 12 receivers that are going to be used as sources during the TR process.
Task 5—Nonlinear Responses Associated with Damage

Preliminary Results: TR Imaging

- The elastic wave energy emitted by the original receivers - now acting as sources and broadcasting the high pass filtered TR signals - refocuses on the crack, giving us a clear indication of where the source of nonlinearity is.
Task 5—Nonlinear Responses Associated with Damage

Next Steps

• Repeat TR process with different sources (we fired a total of 13 sources but did the TR imaging process with only one so far, just to see if it works)

• Put a crack in the formation. Can we image that far with all the layers (casing, cement, formation, fluid, etc.) between the tool and the crack?

• Change frequency. Right now we have used a source signal center at 10 kHz. Can we still image at 5kHz, 1kHz, 100Hz? Lower frequency means larger penetration depth and propagation distance.
Lessons Learned

– Research gaps/challenges: so far, none
– Unanticipated research difficulties: so far, none
– Technical disappointments: so far, none
– Changes that should be made next time: so far, none
Synergy Opportunities

DOE-FE Carbon Storage Program

- **Nonlinear Acoustic Methods for the Detection and Monitoring of CO2/Brine Leakage Pathways in Wellbore Systems** – Pierre-Yves Le Bas & Carly Donahue. Signatures discovered in this project will be shared with our project to guide discovery of signatures with embedded sensor arrays.

- **Novel methods to detect small leaks over large areas** – Youzuo Lin. Some signatures discovered and algorithms developed in this effort may be relevant to our project—lessons learned will be shared.

- **Robust in situ strain measurements to monitor carbon dioxide storage** – Larry Murdoch. Optical methods developed in this effort to measure strain using microwave photonics at higher frequency for acoustic applications will be used by our project.

- **Characterizing and interpreting the in situ strain tensor during CO2 injection** – Larry Murdoch. Strain and changes in in-situ stress resulting from injection evaluated during this project will contribute to understanding wellbore integrity for our project.

LANL Laboratory Directed Research and Development (LDRD)

- **Critical Stress** – Paul Johnson. This project is exploring the physics of systems at a critical state of stress, including many that involve fluid flow. Signatures and insights discovered in this effort will be shared with our project.
Accomplishments to Date

Key Findings:
- The TR Experiments work in a laboratory borehole
- TR NEWS computer simulations show the procedure in full
- Fiber optics have been demonstrated in a tube

Next Steps:
- Begin ‘leak listening’ studies applying machine learning. Laboratory and simulation.
- Advance the fiber optic sensors for borehole use
- Continue simulations
- Test TR+ NEWS in experiment
Appendix: Timeline

11/13/17: GTO Program Review: Paul Johnson, Project Introduction *
11/30/17: Subcontract paperwork with Clemson University complete; sent out for review and approvals
12/21/17: Telecon to discuss timeline for rest of quarter
01/19/18: Paul Johnson, Telecon to introduce background Time Reversal research to the greater project team *
02/01/18: Harvey Goodman, CVX Gorgon Project briefing; CVX needs **
02/15/18: Larry Murdoch, Telecon to introduce Clemson’s Fiber Optic sensing research and their group to the greater project team *
02/26/18: Clemson subcontract awarded and in place ($$)
03/05/18: Telecon to discuss patent research to date
03/10/18: Meeting with CVX and HAL; detecting wellbore leakage **
04/09/18: LBNL visit to LANL; joint telecon with Clemson, fiber optic experiments
04/26/18: Tour of HAL research facilities courtesy CVX **
05/01/18: Beginning LANL TR borehole experiments
06/01/18: Beginning TR NEWS simulations
07/02/18: Telecon: TR NEWS Simulation update
Impact and Tech Transfer

Impact

Development of an autonomous system for long-term monitoring of wellbore integrity and leakage addresses a key cost-driver for post-injection site care.

This system could also have impacts outside of CO$_2$ storage, particularly for subsurface operations concerned with controlling the behavior and control of fluid flow in fracture dominated reservoirs.

Technology Transfer

The participation of Chevron as a collaborating partner on the effort will help to focus our technology development on needs of an end user.

The project team has extensive prior experience engaging commercialization partners on successfully developed technology; we anticipate being in a position to engage commercialization partners by the end of year 3.
Benefit to the Program

- GOAL: development of autonomous system that can be deployed in wells for long-term (e.g., decades), unattended monitoring both wellbore integrity and associated stress changes (Topic Area 2).

- If successful in achieving the overarching R&D goal, the outcome would be a cost-effective option (hardware and software) for long-term autonomous monitoring of wells.

- This technology would have broad application in subsurface operations, where maintaining and monitoring wellbore integrity is central to reservoir management strategies (including geothermal operations, oil/gas operations, injection operations). However, the largest benefit to national subsurface energy interest likely lies in post-closure monitoring of wellbore integrity, as needed for CO2 storage operations. This system would be a cost-effective autonomous option to provide the data necessary to ensure that wellbore integrity is being maintained, targeting a central need in any CO2 storage.
LANL: overall lead
LANL and LBL: TR NEWS simulation and experiment
LANL: Machine learning applied to leak signals, experiment and simulation
Clemson: Fiber optic borehole detection
Chevron: consultation on R and D, and application

Bibliography

• In Progress
Develop an autonomous system for long-term deployment in wells for unattended monitoring wellbore integrity and associated stress changes. The system consists of wellhead and downhole components based on the combined signals of piezoelectric and/or optical sensors. The signal targets include: (i) seismo-acoustic signals associated with moving (leaking) fluids; (ii) the stress field along the wellbore where changes in stress may presage damage and leakage; (iii) nonlinear properties in the near-wellbore region that arise when damage develops and progresses.
