

# **Investigation of Autoignition and Combustion Stability of High Pressure Supercritical Carbon Dioxide Oxy- combustion**

PI: Wenting Sun

Co-PI: Devesh Ranjan, Tim Lieuwen, and Suresh Menon

School of Aerospace Engineering  
Georgia Institute of Technology  
Atlanta, GA 30332

Performance period: Oct. 2015 – Mar. 2019

UTSR Project: DE-FE0025174 PM: Seth Lawson

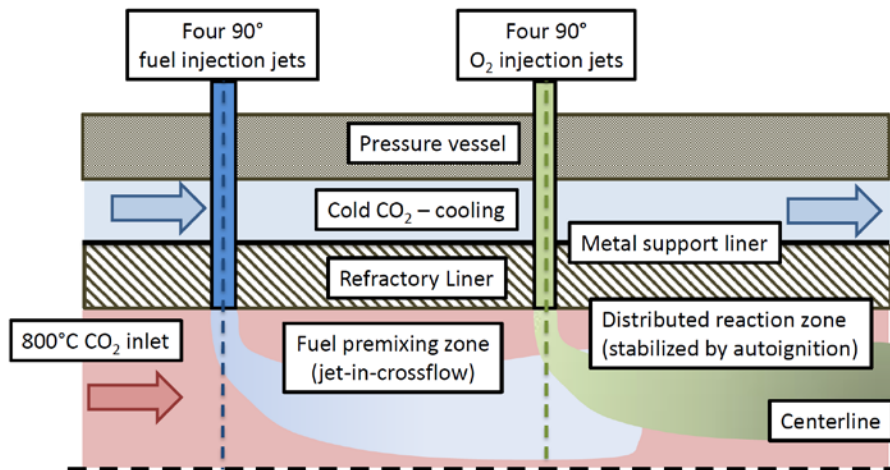

2018 UTSR Project Review Meeting

# Overview of the Scientific Problem

- What fundamental combustion properties/knowledge we need in order to design combustor for  $s\text{CO}_2$  oxy-combustion?
  - Kinetics and dynamics

Fundamental chemical kinetics  
and  
flame dynamics at relevant conditions

## Conceptual combustors

# Kinetic Challenges for sCO<sub>2</sub>-fuel-O<sub>2</sub> Mixtures

Deviation increases with pressure: knowledge gap  
Kinetic models must be validated at regime of interest

CH<sub>4</sub>/O<sub>2</sub>/CO<sub>2</sub> ( 9.5%:19%:71.48%)

H<sub>2</sub>/CO/O<sub>2</sub>/CO<sub>2</sub> (14.8%:14.8%:14.8%:55.6%)

**We know the answer now**

# Overview of the Scientific Questions and Proposed Work

- What is the fundamental kinetic properties?
  - Experimental investigation of chemical kinetics for sCO<sub>2</sub> Oxy-combustion (Task 1&2: Ranjan & Sun)
- How can we use the kinetic model to design combustors?
  - Development of a compact and optimized chemical kinetic mechanism for sCO<sub>2</sub> Oxy-combustion (Task 3: Sun)
- What is the combustor dynamics at this new condition?
  - theoretical and numerical investigation of combustion instability for sCO<sub>2</sub> Oxy-combustion (Task 4&5: Lieuwen, Menon)
- What is the new emission property?
  - At new operating conditions, should we worry about things we didn't need before? (Task 6: Sun)

So what?

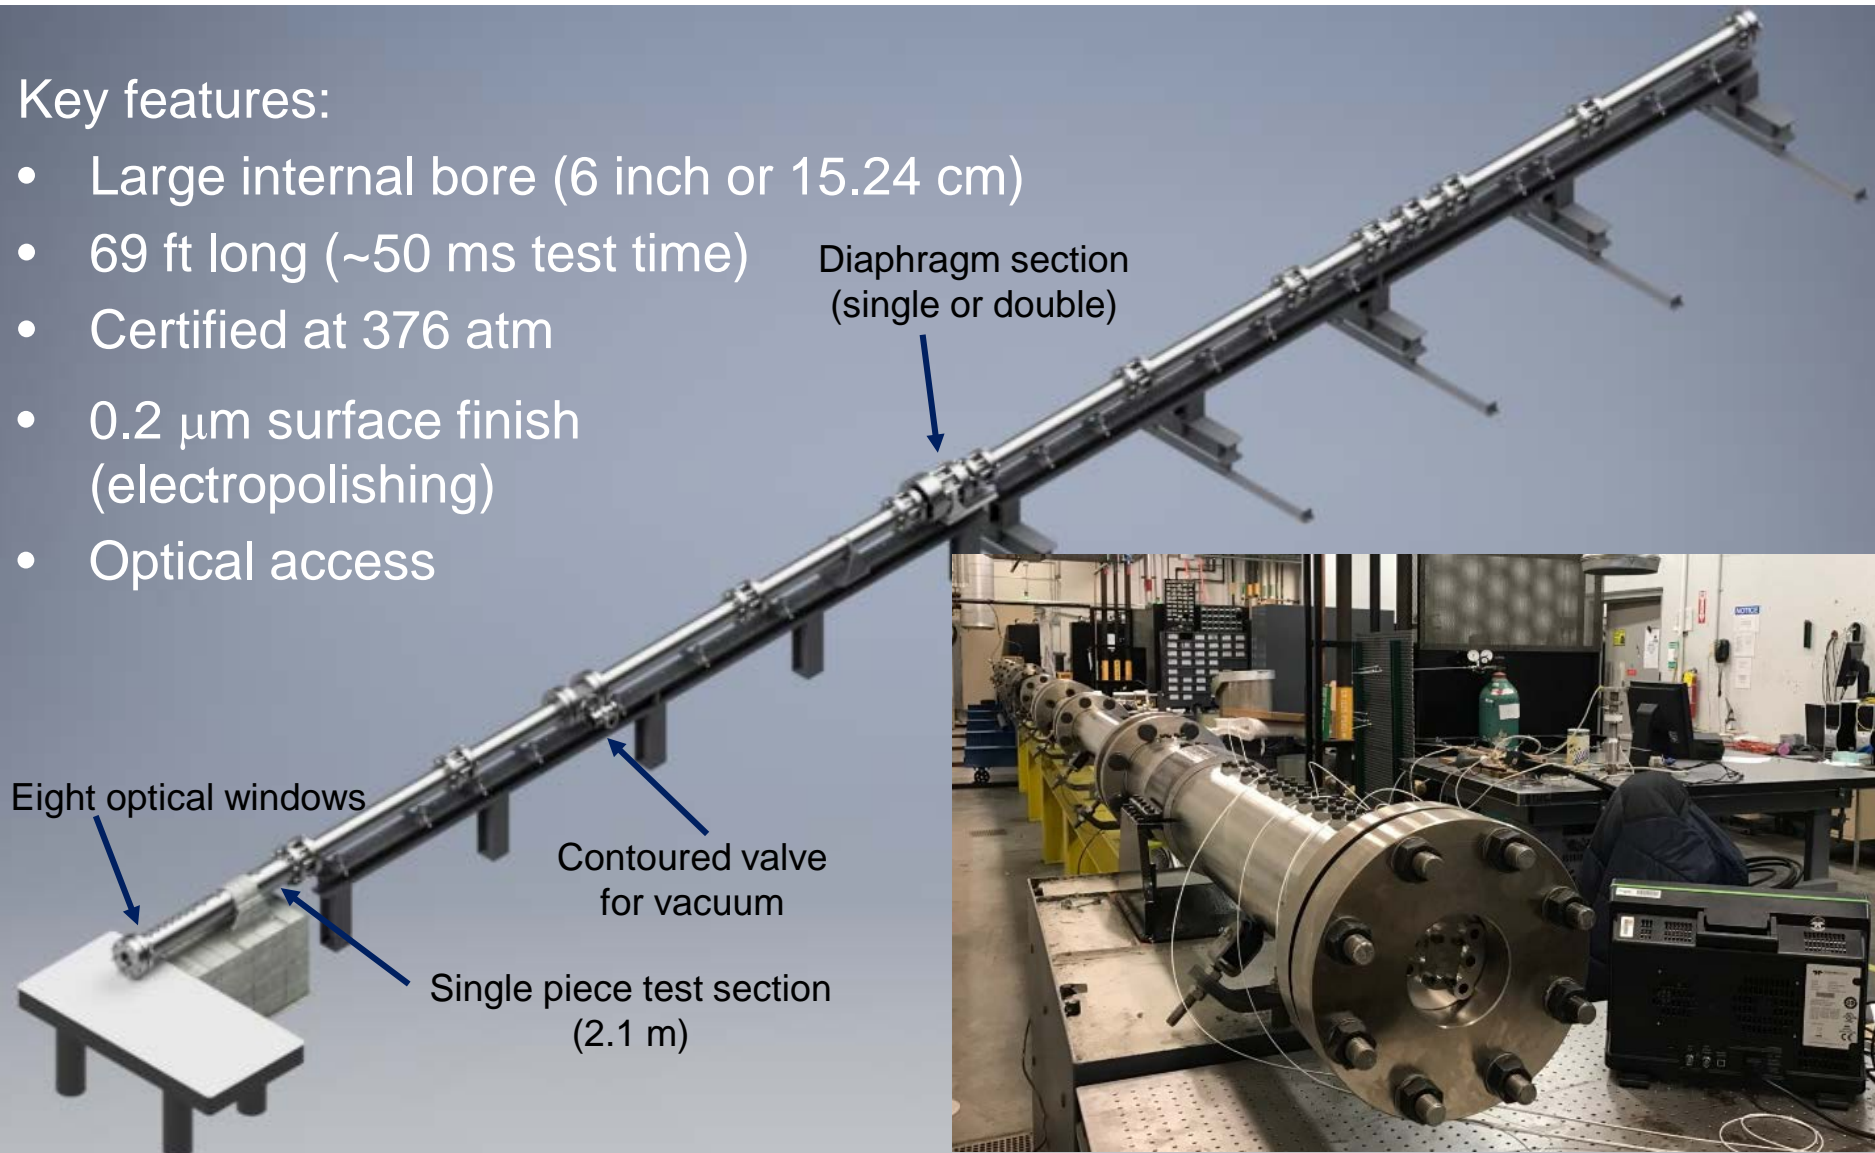

So what?

# Task 1: Development of a High Pressure Shock Tube

## Key features:

- Large internal bore (6 inch or 15.24 cm)
- 69 ft long (~50 ms test time)
- Certified at 376 atm
- 0.2  $\mu\text{m}$  surface finish (electropolishing)
- Optical access

# Task 1: Development of a High Pressure Shock Tube

Driver support frame

CaF<sub>2</sub> window

End wall plugs

Kistler 6045A

Eight circumferential plugs

Five PCB dynamic pressure sensors

Test section

- **Driven section** vacuumed down to  $1 \times 10^{-6}$  Torr using an Agilent IDP-15 Dry Scroll pump and Agilent TwisTorr 304 FS AG turbo pump

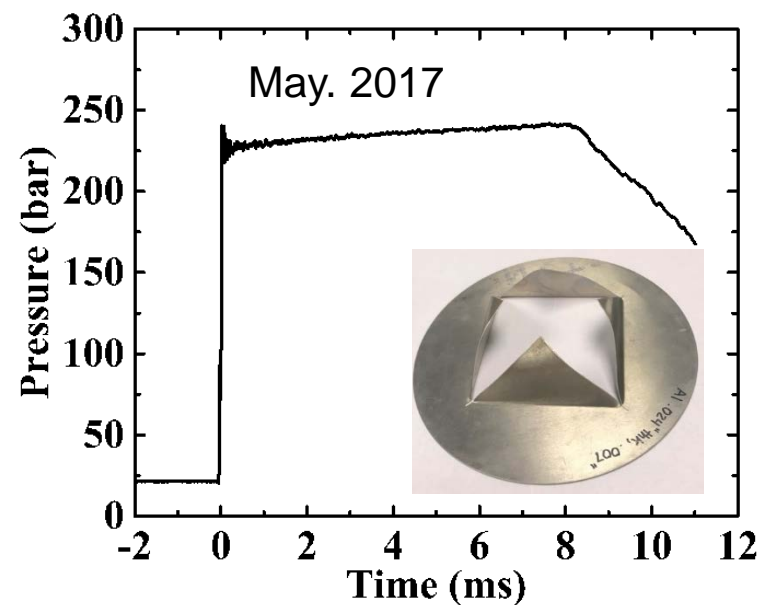

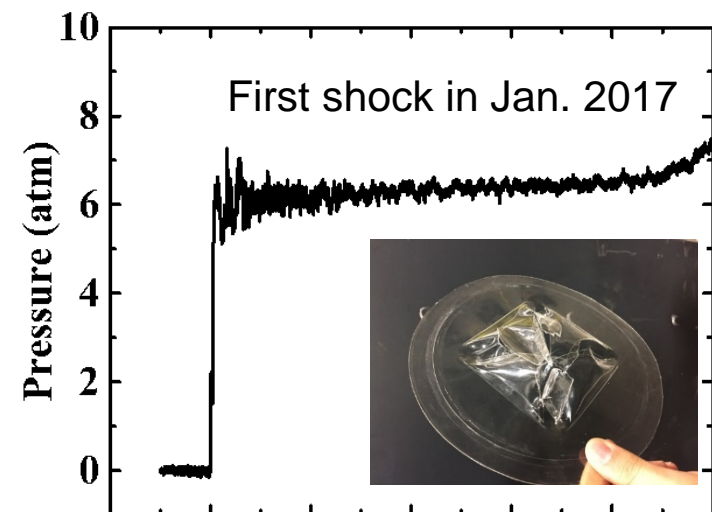

# Task 1: Development of a High Pressure Shock Tube

March 2016

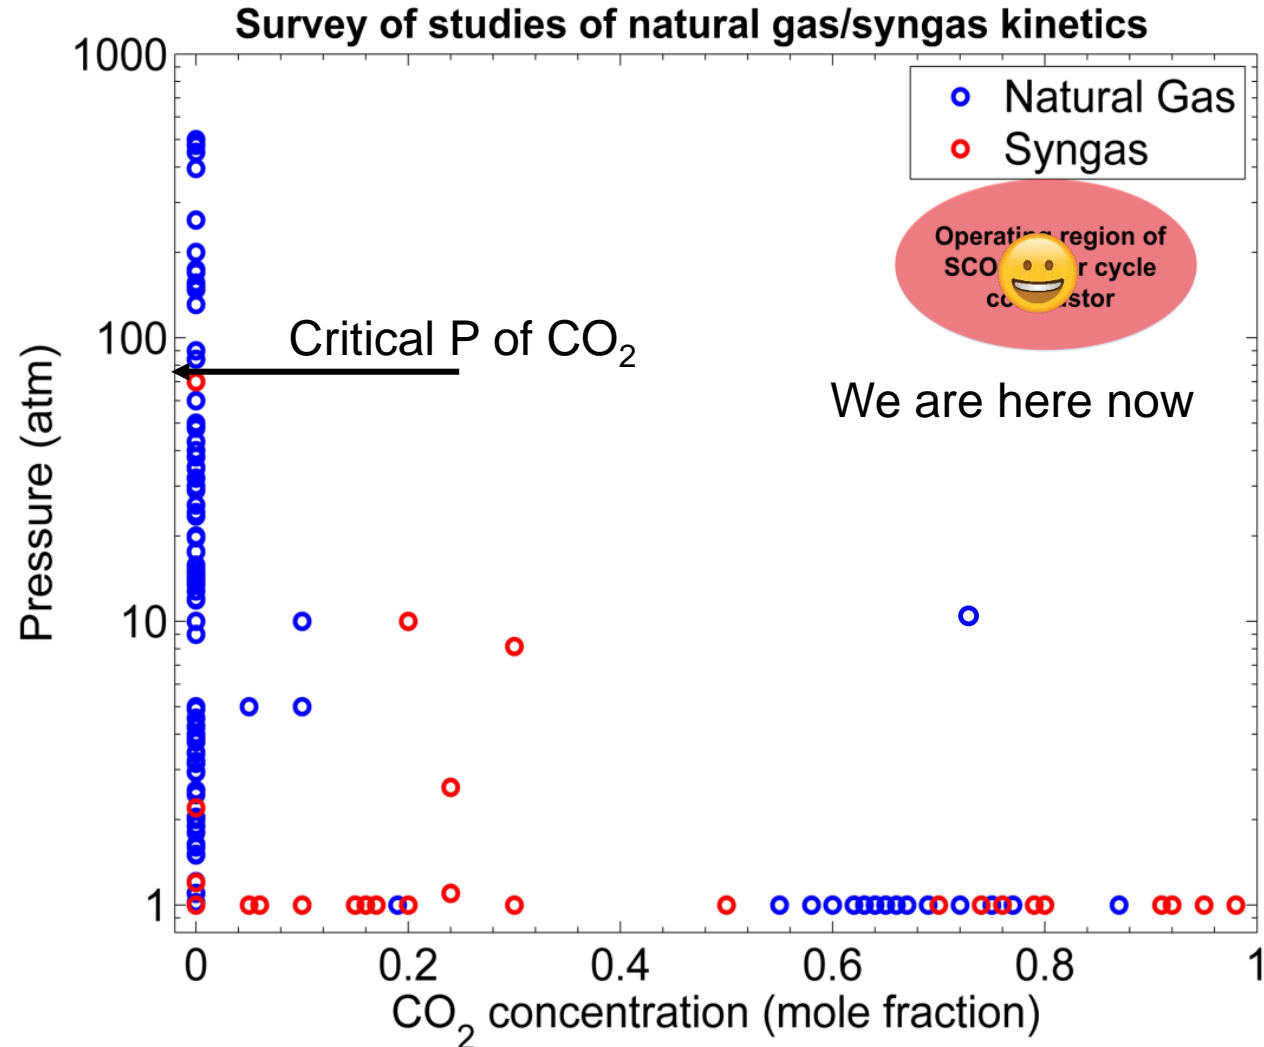

October 2016

# Task 2: Investigation of Natural Gas and Syngas Autoignition in sCO<sub>2</sub> Environment

- No study before in region of interest
- A new regime to explore!
- CO<sub>2</sub> has negligible chemical effect
  - Based on 1 to 15 atm results and simulation using GRI 3.0 and Aramco 1.3
  - GT 17 atm expt. Agreed with Aramco 1.3 using same mixture with Hargis et al.

e.g.:

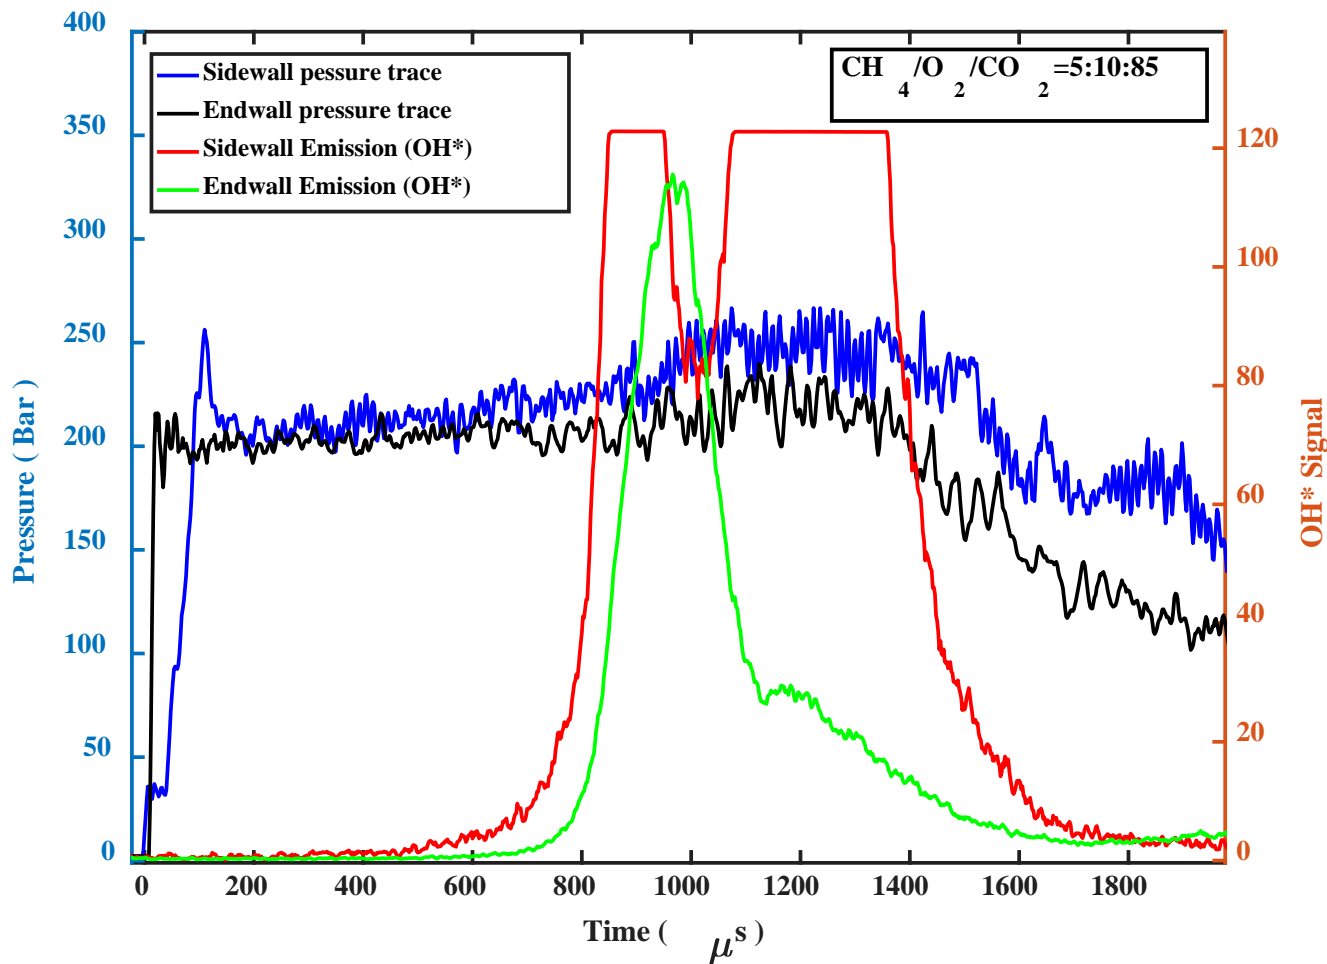

J.W. Hargis, E.L. Petersen, Energy & Fuels, (29) 2015

S. Vasu, D.F. Davidson, R.K. Hanson, Energy & Fuels, (25) 2011

# Pressure Traces in $\text{CH}_4/\text{O}_2/\text{CO}_2$ at 200 bar

# Autoignition Delays at sCO<sub>2</sub> condition

- Pressure: 100±5 bar, and temperature range of 1274 to 1433 K

Simulation results from Aramco 2.0, USC Mech II and HP-Mech are close to each other, however GRI 3.0 predicts a significantly shorter autoignition delay, having approximately a **factor of 3 difference**

# Autoignition Delays of CH<sub>4</sub> in Ar

- Pressure: 95±3 bar, and temperature range of 1248 to 1410 K

No chemical effect from diluent is observed

# Autoignition Delays of CH<sub>4</sub> in CO<sub>2</sub> and Ar

- Pressure: 200±5 bar, and temperature range of 1137 to 1380 K

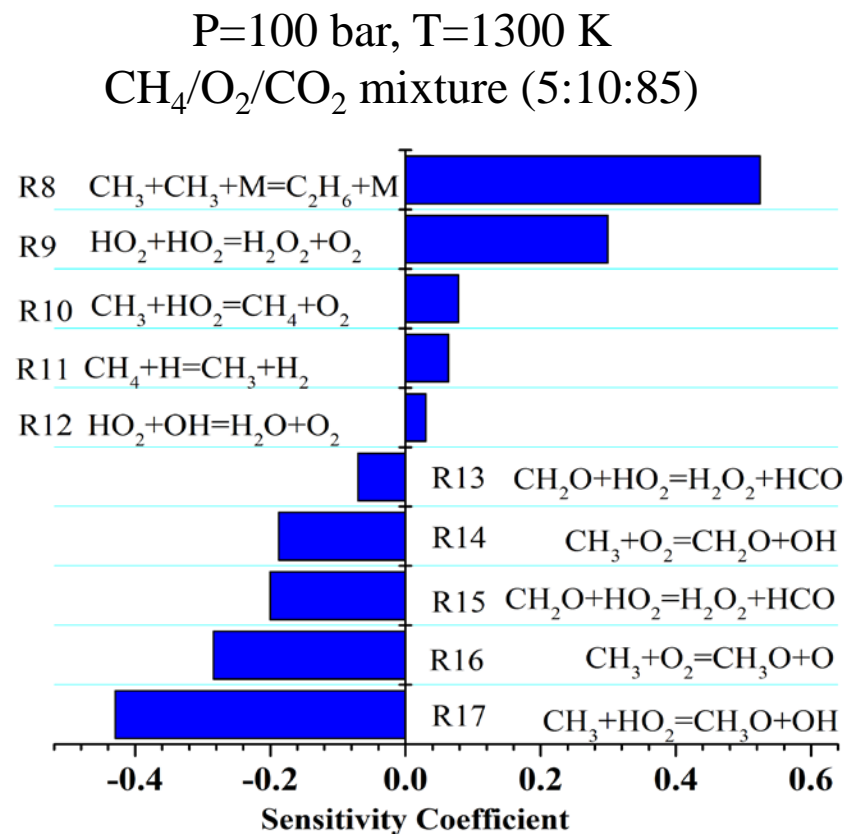

Temperature further distinguishes different kinetic models  
 - High T kinetics is much simpler than low T kinetics

# Chemical Analysis

- Sensitivity Analysis: perturbing reaction rate constant of each reaction, see the response of autoignition delay
- $\text{CH}_3 + \text{CH}_3 + \text{M} = \text{C}_2\text{H}_6 + \text{M}$  becomes to be the most dominant one at high P condition
- Different from low pressure conditions,  $\text{H} + \text{O}_2 = \text{O} + \text{OH}$  is the sixth most dominant reaction to enhance ignition
- The **third body efficiency** of  $\text{CO}_2$  was investigated by simply doubling its value, which has a negligible effect on autoignition, consistent with previous work from 1-15 atm

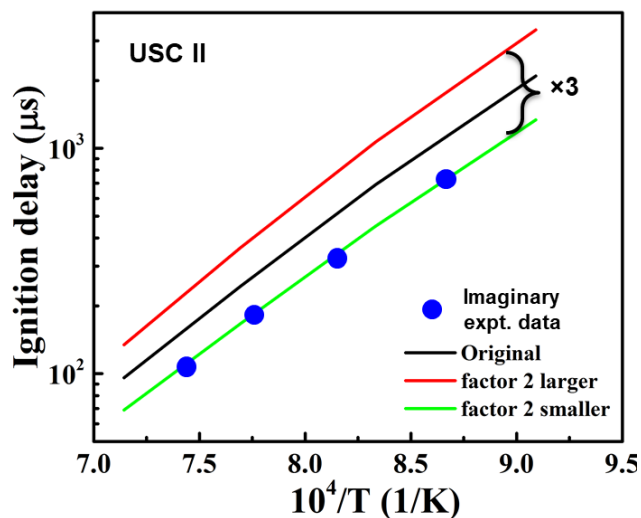

# CH<sub>4</sub> Reaction Pathway Analysis

# CH<sub>4</sub> Reaction Pathway Analysis

- Two reaction pathways
  - (1) CH<sub>3</sub> oxidation to CH<sub>3</sub>O
  - (2) CH<sub>3</sub> recombination to C<sub>2</sub>H<sub>6</sub>
- Autoignition determined by **ratio of (1)/(2)**
- Ratio of (1)/(2): USC II: 0.94; Aramco: 0.95; GRI: 4
- First target for mechanism optimization

The rate constant of  
 $\text{CH}_3 + \text{CH}_3 = \text{C}_2\text{H}_6$   
 Determines  $\tau_{\text{ig}}$

It is already optimized

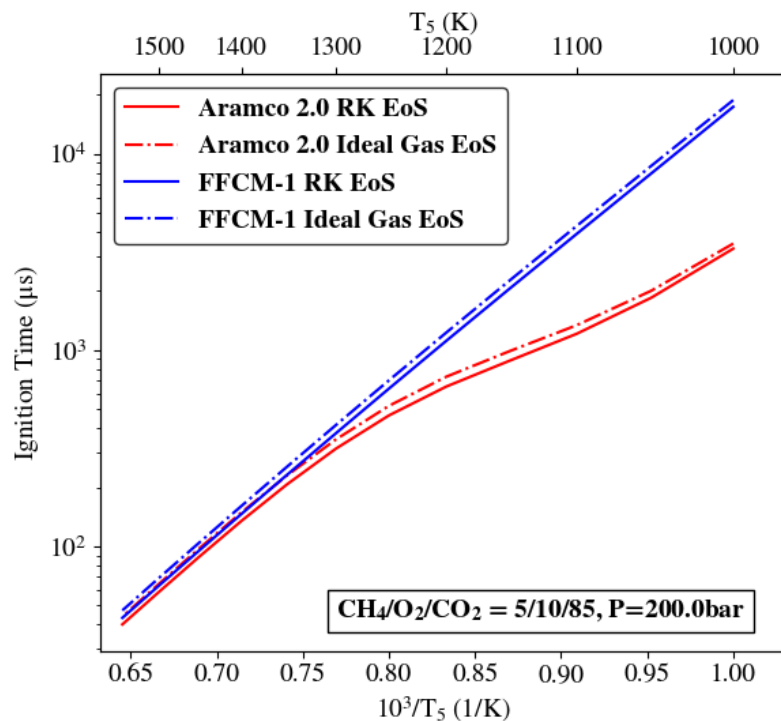

# CH<sub>4</sub> Reaction Pathway Analysis

# Does Real Gas Effect Matter?

- Not here, but it depends.....

Real gas impacts on ethane profile  
 $\text{C}_2\text{H}_6/\text{O}_2/\text{Ar}$  @ 1300 K

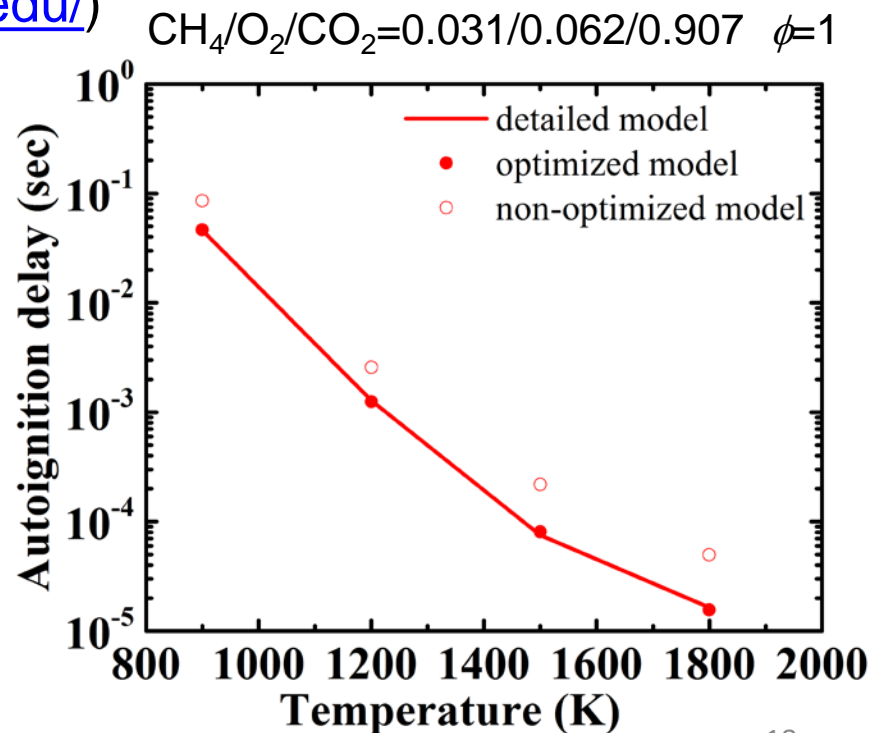

Tang et al., IJCK 2006

- At high T (away from critical T), real gas behaves like ideal gas
- At low T (close to critical T), real gas effect is important

# Task 3: Development of a Compact and Optimized Chemical Kinetic Model for sCO<sub>2</sub> Oxy-combustion

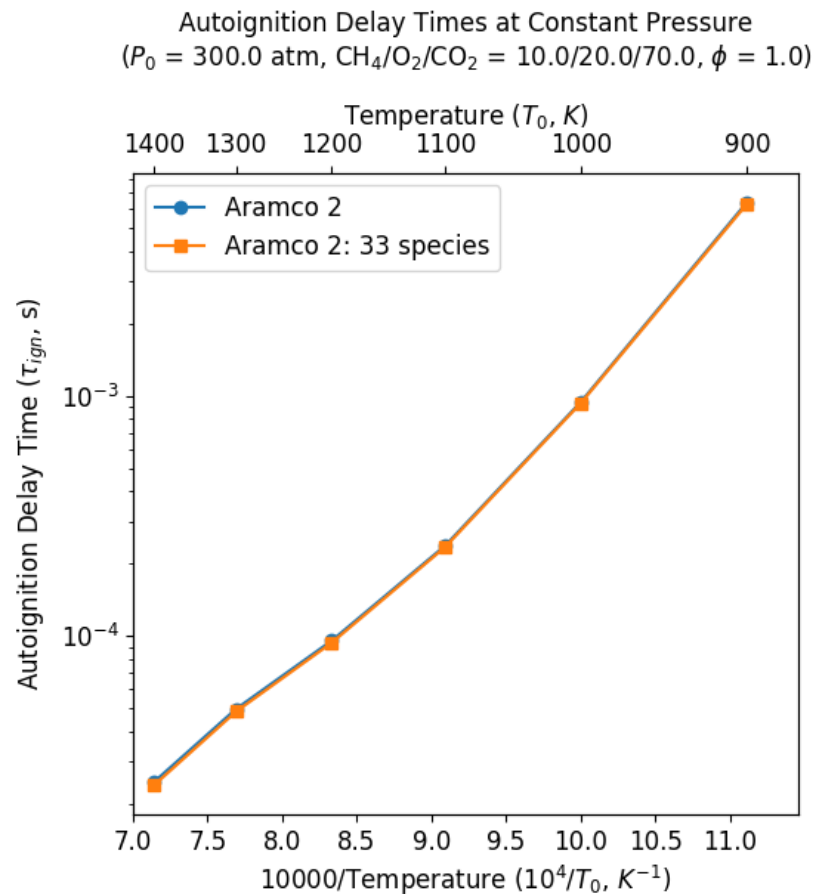

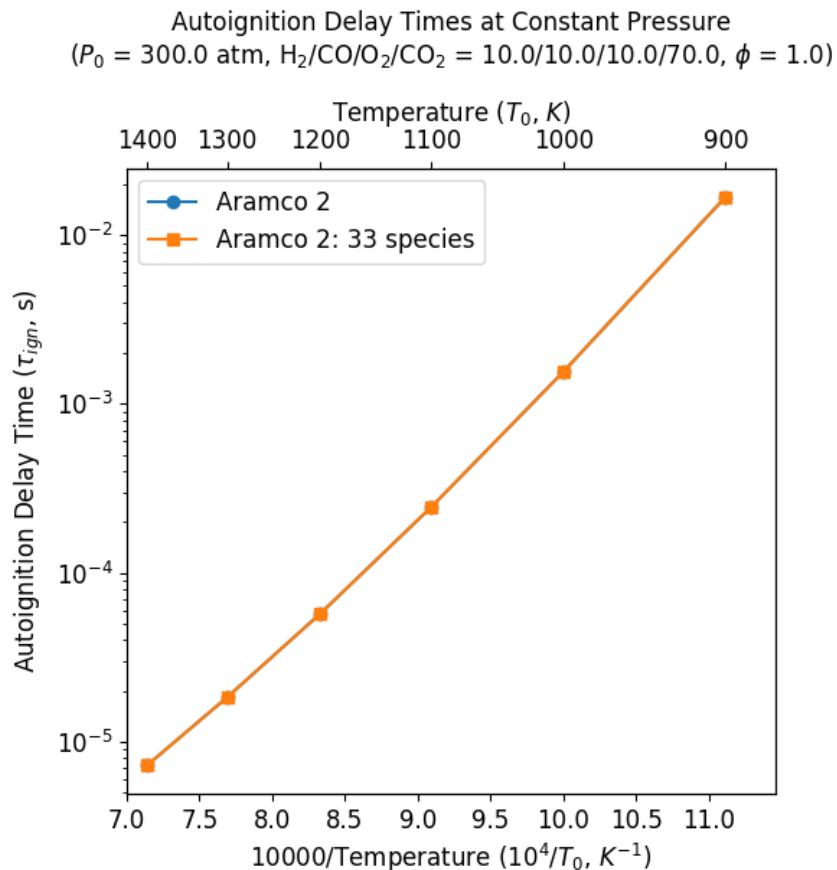

- USC II (111 species), Aramco 2.0 (493 species) can't be used in CFD
- 1<sup>st</sup> step is model reduction
  - GPS (<http://sun.gatech.edu/download.htm>)
  - Chem-RC (<http://engine.princeton.edu/>)
- A 27 species reduced mechanism<sup>1</sup> for natural gas and syngas is developed from USC II (still too large for CFD)
- A new 13 species model was developed with optimization
  - Covers 900 K to 1800 K, 100 atm to 300 atm
  - Max 12% deviation

# Task 3: Development of a Compact and Optimized Chemical Kinetic Model for sCO<sub>2</sub> Oxy-combustion

- A 33 species reduced kinetic model for natural gas and syngas is developed using Aramco 2.0 (493 species)
  - Number of species is condition dependent: covers 900 K to 1800 K, 150 atm to 300 atm
  - Max 10% deviation

# Task 6: Emission Properties of sCO<sub>2</sub> Oxy-combustion

- It seems pressure does not affect much in kinetics because model can predict ignition delays well
- Here comes the problem caused by pressure...

After 200

CH<sub>4</sub> diffusion flame

Micro-tubes  
High Pressure sCO<sub>2</sub>

Annular Space  
Low Pressure sCO<sub>2</sub>

From Thar Energy, UTSR workshop 2015

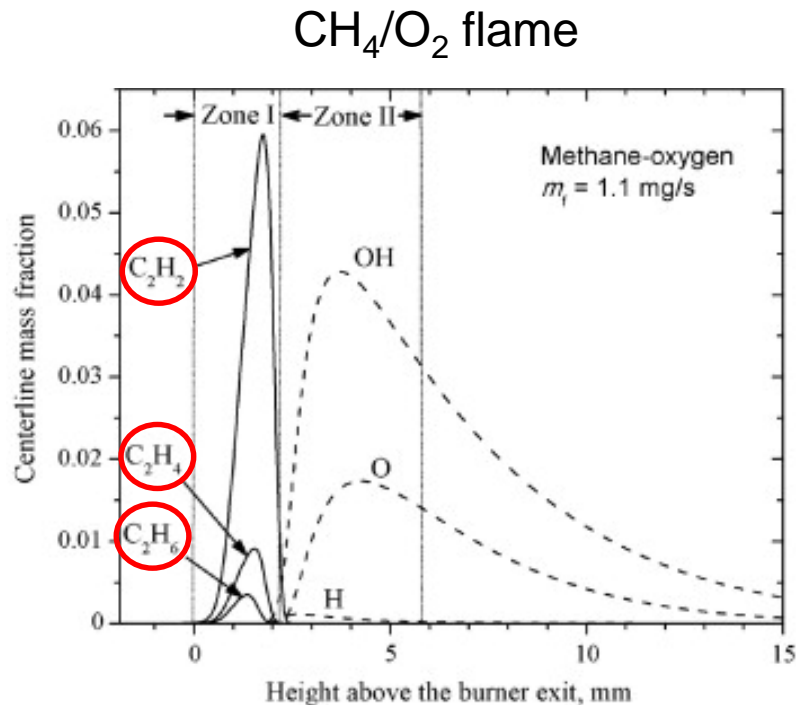

100 atm

# Task 6: Emission Properties of sCO<sub>2</sub> Oxy-combustion

- Soot Formation Mechanism in High Pressure CH<sub>4</sub> Flame

- Conclusion from our work:
- $CH_3 + CH_3 + M = C_2H_6 + M$  becomes to be the dominant at high P condition

- Then  $C_2H_6$  promotes soot formation

Joo, Peter H., et al. *Combustion and Flame* 160.10 (2013): 1990-1998.

# Task 6: Emission Properties of sCO<sub>2</sub> Oxy-combustion

- Analysis of deposits from shock tube experiments

Preliminary results:

- Composition: C/O $\approx$ 3/1 (typical value owing to partial oxidation)
- Chemical bond: C-C or C=C (~60%); C-O (~36%)

# Recap of kinetic investigation

- GRI 3.0 fails at high pressure
  - It is compact and has NO<sub>x</sub> module included, but it does not work at high pressure ( $P > 100$  bar)
- Aramco 2.0 agrees with experiments very well through the temperature range of tests. HP-Mech works too.
- FFCM-1, USC II work well at high temperature region ( $T > \sim 1200$  K), but their predictions deviate with experiments when  $T < \sim 1200$  K because of the missing  $\text{CH}_3\text{O}_2$  kinetics
- CO<sub>2</sub> has no chemical effect on ignition kinetics
- Significant particulate formation observed at high  $P$ , probably owing to partial oxidation (study ongoing)

# Task 5: LES Studies of Supercritical Mixing and Combustion

**Baseline model  
NOT actual design**

- Mixing and flame stability
- Systematic variation of design parameters
  - Momentum ratios for fuel and oxygen, flow rate, number of jets
  - Size, spacing, and locations of injectors
- Computational modeling may be more cost effective but include its own challenges
  - Kinetics
  - Turbulence-chemistry closure
  - Real gas effects

# Task 5: LES Studies of Supercritical Mixing and Combustion

## Instantaneous Reacting Flow Features

- Autoignition close to predicted location based on mixing
- Autoignition occurs slightly downstream of the oxidizer jet towards lean side
- Autoignition with lifted flame structure

Temperature iso-surface (2100 K, 1500 K)

Vorticity magnitude colored by temperature

# Instantaneous Reacting Flow Features

Schlieren

Temperature

- Large density gradient (Schlieren: log of density gradient)
- Mixing of fuel and oxidizer followed by ignition in lifted regions
- Autoignition in hot kernels where fuel mixes with oxidizer
  - Finite-size kernel but no continuous flame structure
- Autoignition sensitive to many parameters: mixing time, kinetics, local scalar dissipation rate, etc.

# Autoignition and Blow out

Temperature 300 850 1400 1950 2500

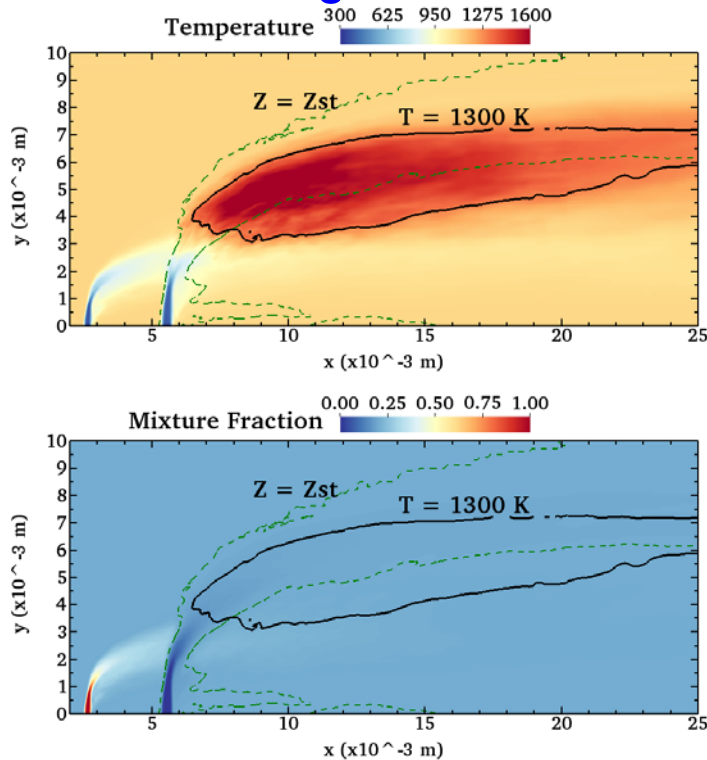

Temperature 300 850 1400 1950 2500

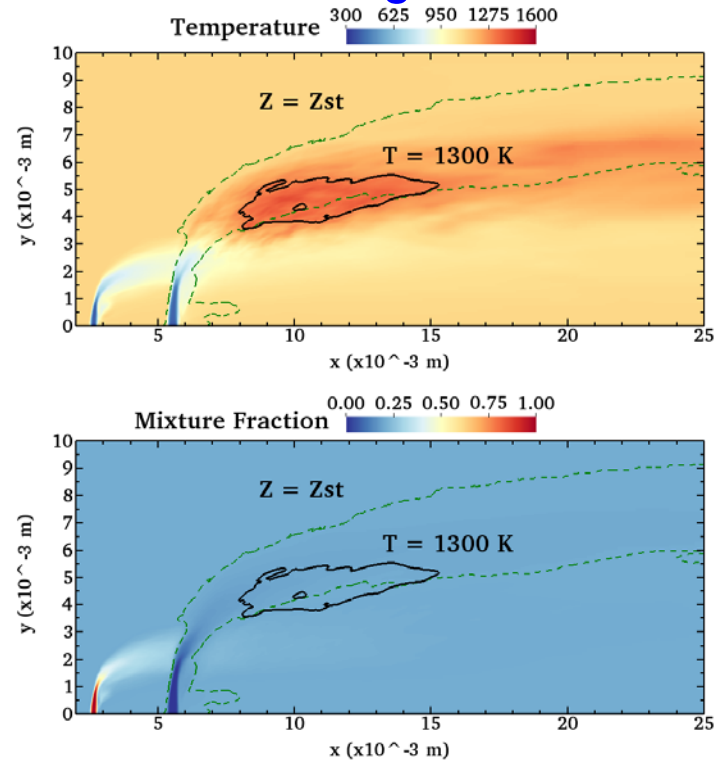

- Possible upstream influence of acoustic waves

# Real Gas Effect

## Real gas EOS

## Perfect gas EOS

- Reduced jet penetration with perfect gas EOS in comparison to Peng Robinson EoS – clearly shows RG effects
- Heat release also decreased with perfect gas EOS

# Flame Length and Combustion Efficiency

- **Combustion is not efficient**
- Combustion efficiency estimated as:
 
$$\eta = 100 \times \frac{\dot{m}_{f,in} - \dot{m}_{f,out}}{\dot{m}_{f,in}} \sim 49\%$$
- Flame length,  $L_f \sim 14.5 D_{ox}$ 
  - estimated as intersection of  $Z = Z_{st}$  and  $T = 1500$  K
- $\eta$  needs to be improved
  - Inflow realistic turbulence
  - Modify J and jet spacing
  - Mass flow rate changes
  - Jet-staging and distributed mixing
  - **Inflow swirling**
- **Mixing is the key**
- Use network modeling for rapid assessment

Temperature overlaid with stoichiometry line

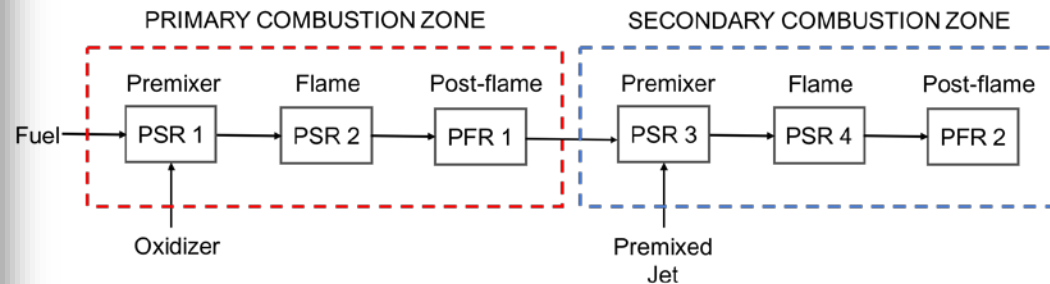

# Chemical Reactor Network (CRN) Modeling

- A viable computationally affordable alternative for parameter study

**Axially staged premixed combustion device [Ahrens et al. (2014)]**

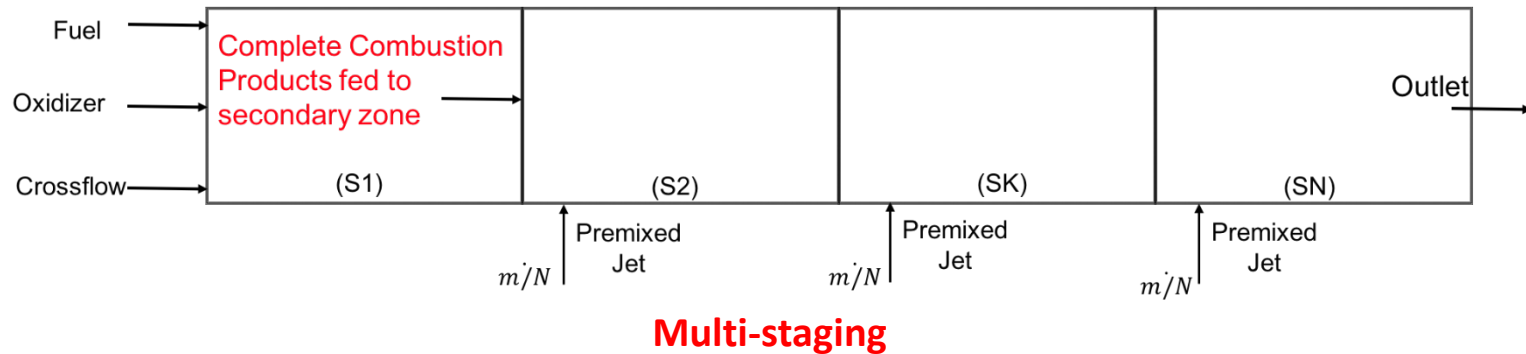

**CRN Model**

- A two-stage premixed combustion device
  - where the fuel/air mixture is split across primary and secondary combustion zones
- Setup essentially is reacting jet in a hot crossflow
- CRN model: 2 PSRs and 1 PFR for each of the combustion zone

# Effect of Staging on CO Emissions

Number of jets	Outlet: T	Outlet: CO	Outlet: CO <sub>2</sub>
1	3332.9 K	0.0091	0.279
2	2675.6 K	0.0078	0.227
3	2379.9 K	0.0011	0.190
4	2334.5 K	0.0010	0.151

- Effect of number of stages on temperature and concentration of CO and CO<sub>2</sub> is examined
- With increase in number of stages, CO emission tends to reduce, which is consistent with experimental studies

# Task 4: Analytical modeling of Supercritical Reacting Jets in Crossflow

- Analytical framework for reacting jets in cross-flow
  - connect flow dynamics to flame dynamics
  - Modeling explicit flame position dynamics
  - Modeling spatially integrated heat release dynamics as a function of flame position
- Understanding flow dynamics of a jet in cross-flow
  - provide key inputs to the velocity field used in the analytical model

CFD with large kinetics is pain...

Analytic model of jet in crossflow

# Non-premixed Flame Position Dynamics

- Task outcome: PDE for flame position fluctuations & solution
- **Wrinkle convection**
  - Flow based convection of flame “wrinkles”
- **Reactive nature of wrinkle generation**
  - From diffusion based physics that drives the mean flame position
- Local flow fluctuations serve as source of “wrinkles” (RHS)

$$\frac{\partial \xi_{1,n}}{\partial t} + u_{x,0} \frac{\partial \xi_{1,n}}{\partial x} - u_{x,0} \left( \frac{d^2 \xi_0}{dx^2} \left/ \left\{ \frac{d \xi_0}{dx} \left( 1 + \left( \frac{d \xi_0}{dx} \right)^2 \right) \right\} \right. \right) \xi_{1,n} \\ = -u_{x,1} \left( \frac{d \xi_0}{dx} \left/ \sqrt{1 + \left( \frac{d \xi_0}{dx} \right)^2} \right. \right)$$

$$\xi_{1,n}(x,t) = \int_0^t u_{n,1}(x,t') dt' - \int_0^{t - \frac{x}{u_{x,0}}} u_{n,1}(0,t') dt'$$

- Governing Physics in solution
  - Time history of local disturbances
  - Disturbances convected from inlet
- Allows comparative analysis with premixed flames for both laminar and turbulent framework

# Understanding JICF from Measurements

- Focus: Shear layer vortices (SLV)
  - leading-edge and lee-side
  - SLV behavior contributes to near-field and pre flame entrainment and mixing
  - SLV rollup and distort to form the CVP, major topological feature which governs **mixing**
- Use measured data from JICF experiments to characterize SLV
  - Stereo PIV flow measurements
  - OH-PLIF flame measurements
  - Compare reacting and non-reacting cases for JICF SLV behavior

# JICF Stability – Representative Results

## Non-reacting cases

$J = 5, S = 1.0$

$J = 25, S = 1.0$

## Globally unstable behavior

- Global jet oscillations
- SLV formed near jet exit

## Convectively unstable behavior

- Suppressed SLV formation
- Vortex growth/pairing

## Reacting cases

$J = 5, S = 1.0$

$J = 5, S = 0.4$

## Factors that govern SLV behavior:

- Jet momentum flux ratio,  
 $J = \frac{\rho_j u_j^2}{\rho_\infty u_\infty^2}$
- Jet to crossflow density ratio,  $S = \frac{\rho_j}{\rho_\infty}$

Reacting cases which should show globally unstable behavior based on  $S$  and  $J$  show convectively unstable SLV structure

Suppressed SLV behavior

Flame weakens mixing

# Summary of Accomplishments

- High pressure shock tube developed and commissioned
- IDT measurements at relevant conditions validated kinetic models
- Reduced/optimized kinetic models developed and implemented in CFD
- Theoretical framework developed for JICF
- LES framework and investigation of JICF
- **Recommendation on combustor design:**
  - Mixing is critical and challenging: efficiency & emissions (watch out!)
  - Low T region is challenging both physically and chemically

# Thank you! & Questions?

Acknowledgement:

UTSR Project: DE-FE0025174; PM: Seth Lawson

# Challenges of Experiments at sCO<sub>2</sub> Condition

- Large  $C_p$  of CO<sub>2</sub>
  - Strong shock needed for CO<sub>2</sub>
- BL is much thicker with CO<sub>2</sub>
  - Non-ideal effect
- ID of shock tube must be large
  - 150 mm
  - High experimental cost

J. Hargis & E. Peterson, E&F, 2015  
K. Grogan & M. Ihme, PROCI, 2016

# Shock Tube Development - mixture preparation system

High accuracy Baratrons (**0.05%**) to measure partial pressure for mixture preparation

Turbo molecular pump

MicroGC to monitor compositions

Magnetic stir to promote mixing

# Signal from End wall Needed

Simultaneous sidewall and end wall traces and emissions  
Small difference between end wall and sidewall signals: “good chance” as  
quasi-homogeneous ignition event

# Vapor-Liquid Equilibrium in Supercritical Mixtures

- Single species: the phase is uniquely defined by the **equilibrium diagram**
- **Subcritical regime**: jet exhibits atomization, droplets, and sharp gas/liquid interface
- **Supercritical regime**: Interface is diffused and no droplet formation
- Mixtures: VLE exists at interface for given  $(p, T)$  and composition  $z_i$ .
- JICF can have local VLE regions in
  - $\text{CH}_4\text{-CO}_2$ ,  $\text{O}_2\text{-CO}_2$  interfaces
  - $\text{CH}_4\text{-O}_2\text{-CO}_2\text{-H}_2\text{O}$  regions
- Critical properties of each component play a crucial role to determine VLE
- Need to include VLE effects to account for mixture effects
